

Philosophical Fundamental Problems

Festschrift for the University's Four-Hundredth Anniversary

R. Nielsen

Translated from the Danish

Copenhagen: Gyldendal, 1879

Philosophy does not, like other sciences, enjoy the advantage of being able to build upon immediately firm presuppositions, upon indisputable fundamental principles; for in the whole of philosophy there is not a single proposition that stands so firm that it cannot, when treated on its own, be assailed by criticism and dissolved in dialectic. For that reason philosophy cannot very well parcel out its proofs in the way that mathematics, for example, can. Although mathematical proofs must be presented in strict order if full, scientific insight is to be attained, the mathematician nevertheless does not expose himself to any essential misunderstanding if, for one purpose or another, he treats a particular problem in isolation. Those who are competent know how the presuppositions can be proved, and those whose prior knowledge does not suffice content themselves with the result of the demonstration, trusting that the foundation is firm. But upon such a trusting acquiescence the philosopher, it lies in the nature of the case, dare not reckon. In philosophy no proof can stand alone; the treatment of a separate part must borrow its light from the whole, and the comprehensive system-proof must, so to speak, be transparent in every single demonstration. But it is now well known from the history of philosophy that the systems succeed one another, so that the preceding ones always fall before those that follow. This is indeed to some extent the case in the other sciences as well, but with the—admittedly very significant—difference that certain discoveries, methods,

and modes of proof either remain unassailed or at least, under a further-reaching elaboration, yield points of support, recognizable points of departure for further progress. It is otherwise in philosophy. Here a new point of view, a new thought, a new idea cannot step out into the world as a physical or natural-historical discovery can. When a philosophical system, with its principle and its peculiar method, falls prey to critical dissolution and loses its standing, the whole is recast in such a way that, in the new casting, one can hardly recognize what the abiding element really is that the preceding system deposited. If one regards the matter exclusively from this side, one would be tempted to believe that philosophy was no true science. But the view is one-sided and therefore misleading; the misleading element lies in the fact that one takes one's models from other sciences and applies a standard that does not fit. Philosophy must necessarily have its ideal peculiarity; what essentially belongs to the invisible world of thoughts cannot possibly bear the same marks as that which can be demonstrated from piecemeal-positing conditions or exhibited in visible facts. Seen, on the contrary, from the standpoint of the development of thought and of a consciousness growing in clarity, it shows itself that philosophy, in steady historical continuation, labors at the solution of certain ever-recurring problems; that every thinker who, by placing one or more of these problems in a light advantageous to inquiry, has made a contribution to the solution, remains standing as an eminent figure in the history of philosophy; and that his contribution continues to have effect, even though his school has long since ceased to exist. For a closer understanding of this, and in order, if possible, to contribute to a somewhat clearer conception of philosophy as a science, attention is directed to the problems set forth below.

I. The Problem of Knowledge

Among the philosophers who in more recent times have treated the question of the conditions and limits of human knowledge, Imm. Kant indisputably occupies the first place—if not by the results to which his inquiries led him, then at any rate by the manner in which he has posed the problem. Earlier thinkers—whether, like Locke, they laid the emphasis on the senses, or, like Leibniz, on the understanding—simply

presupposed that we know from experience what experience is, that experience is something that is understood of itself; but Kant's "*Kritik der reinen Vernunft*" shows that experience precisely is *not* something that is understood of itself, that in order to discover which cognitions we can draw from the sources of experience, we must go back to the inviolable fundamental conditions of cognition and begin with the question of *the possibility of experience*.

It is evident that the presuppositions which the knower himself must bring with him in order to be able to make an experience cannot be borrowed from experience, even though it is only with the help of experience that they can come to consciousness. What, then, are these presuppositions? Without sensation it is impossible to apprehend the sensible, and without understanding impossible to determine what is sensed: experience is conditioned by sensation and thought; but by what is sensation conditioned, and how does it stand with the understanding? All sensation rests upon an intuiting. To sense an object in space is just as impossible without the intuition of space as it is impossible to apprehend a change in time without the intuition of time. The pure intuitions, *space and time*, are therefore a priori necessary presuppositions for all sensation and thereby for all experience. In order to procure a positive content, thought must attach itself to sensation; for the understanding is no intuiting faculty, and the old metaphysics' attempts to open up for itself a supernatural world and, by pure understanding, to make discoveries of supersensible things are fantastical. But that sensation cannot bring it about that any experience whatever is made without the assistance of the understanding is seen from this: that the one sense-impression cannot be distinguished from the other without a discriminating activity, and the one representation is not determined by the other without a judging activity. The judging understanding would not be able to exercise its activity if it did not itself contain *a priori* those root-concepts, categories, by which logical judgments must necessarily be conditioned. Which these categories are, and how many they are, can be seen from the division of judgments in formal logic. Thus the hypothetical judgment shows itself to be grounded in the categories of cause and effect, and the disjunctive in the category of reciprocity. The a priori categories of the understanding are therefore indispensable for all thought and thereby for all experience.

The pure sense-intuitions and the a priori concepts must necessarily be fundamentally different, indeed heterogeneous, since the senses are heterogeneous with the understanding; the question then arises how it is possible that forms so heterogeneous can be united in the cognizing consciousness. We are referred to the imagination, which, on the one side intellectual, on the other side sensible, by means of the intuition of time, furnishes an a priori schema necessary for the possibility of experience. It is not enough, for example, to have assured oneself of the validity of the concept of cause as a concept alone; here a condition is required for the concept's application to the appearances in the sensible world, whereby the determinate order of time acquires decisive significance.

By pointing out the subjective fundamental conditions holding for all experience, Kant found himself able to overcome D. Hume's empirical skepticism. Hume rejected the concept of cause as a kind of habit-concept to which no experience corresponds. That things accompany and succeed one another we can experience, but that the one is cause of the other we cannot experience; what we by habit call cause is as unknown to us as what we call force. Kant grants Hume this much, in that he demonstrates the absurdity of wishing to derive the concept of cause from experience; but inasmuch as he at the same time proves that no experience whatever is possible without the concept of cause, he asserts victoriously and once and for all this concept's a-priori-empirical validity so emphatically that, according to him, experience and cause must be said to stand and fall with one another. In particular cases of experience it can often be doubtful what the cause is of an event that takes place. When A, B, and C are accompanied by D, it may perhaps be A, perhaps B, perhaps C, perhaps A and B, perhaps A and C, perhaps B and C, perhaps A, B, and C in conjunction, in which the cause of D is to be sought; for the decision of such doubtful cases one may employ induction, but induction precisely presupposes that there must be a cause.¹

¹“Zwar scheint es, als widerspreche dieses allen Bemerkungen, die man jederzeit über den Gang unseres Verstandesgebrauchs gemacht hat, nach welchen wir nur allererst durch die wahrgenommenen und verglichenen übereinstimmenden Folgen vieler Begebenheiten auf vorhergehende Erscheinungen, eine Regel zu entdecken, geleitet worden, der gemäss gewisse Begebenheiten auf gewisse Erscheinungen jederzeit folgen, und dadurch zuerst veranlasst worden, uns den Begriff von Ursache zu machen. Auf solchen Fuss würde dieser Begriff bloss empirisch sein und die Regel, die er verschafft: dass Alles, was geschieht, eine Ursache habe, würde eben so zufällig sein, als die Erfahrung selbst; seine Allgemeinheit und Nothwendigkeit wären alsdenn nur angedichtet und hätten keine wahre allgemeine Gültigkeit,

Here, be it noted, there is no question of the relation between the cause and the thing itself, which falls outside our consciousness, but only of the necessity of the concept of cause for our experience. An arbitrary play of sensations and representations is only of subjective significance and yields no experience. If a set of terms a, b, c, d, and so forth were incessantly to alter their order and mutual position without any conceivable ground whatever, we should indeed be compelled to apprehend these changes in time, but the temporal succession would give us no concept of cause and, as a matter of course, no experience either. If the image of a house, for example, changed every moment in such a way that now it turned its ridge downward, now upward, and, by the transposition of its parts, took on the shape now of a tower, now of a whale, then we should have to seek the ground of the changes in our own imagination and could in no way refer such an image to any object of experience. For the sake of experience there must be something that compels us to place the one before and the other after; it is, in other words, the necessarily determinate order of time that expresses the relation between cause and effect. The necessity is *a priori*, for it is a conceptual necessity; with this necessity the object is determined by experience, and experience by the object.²

From this one will understand that Kant, with inflexible rigor of consequence, must make a divorce between the object of experience (the phenomenon) and the thing in itself. There must be something that, independently of us, gives our empty forms of cognition—the sensible as well as the intellectual—a real content and determines our apprehension of the object; but that the object, as we apprehend it, cannot possibly be identical with the thing itself is a straightforward consequence of the fact that,

weil sie nicht *a priori*, sondern nur auf Induction gegründet wären... Freilich ist die logische Klarheit dieser Vorstellung einer, die Reihe der Begebenheiten bestimmenden Regel, als eines Begriffs von Ursache, nur alsdenn möglich, wenn wir davon in der Erfahrung Gebrauch gemacht haben; aber eine Rücksicht auf dieselbe als Bedingung der synthetischen Einheit der Erscheinungen in der Zeit, war doch der Grund der Erfahrung selbst und ging also *a priori* vor ihr vorher." Kritik der rein. Vernunft. Leipzig 1838. S. 201.

²⁴Der Begriff, der eine Nothwendigkeit der synthetischen Einheit bei sich führt, kann nur ein reiner Verstandesbegriff sein, der nicht in der Wahrnehmung liegt, und das ist hier der Begriff des *Verhältnisses der Ursache und Wirkung*, wovon die erstere die letztere in der Zeit, als die Folge, und nicht als etwas, was bloß in der Einbildung vorhergehen (oder gar überall nicht wahrgenommen sein) könnte, bestimmt. Also ist nur dadurch, dass wir die Folge der Erscheinungen, mithin alle Veränderung dem Gesetze der Causalität unterwerfen, selbst Erfahrung d. i. empirisches Erkenntniss von denselben möglich; mithin sind sie selbst als Gegenstände der Erfahrung, nur nach eben dem Gesetze möglich." Anf. Skr. S. 196–97.

in passing through our subjective media of cognition, it must necessarily take on a subjective tinge. Our apprehension of the thing is an alteration of the thing: we see objects through colored spectacles.

The sharp separation between the thing in itself and its appearance finds recognition in the exact sciences, particularly in the physiology of the sense-organs. Helmholtz has³ emphatically stressed that our images and representations are effects which the intuited and represented objects produce upon our nervous system and thereby upon our consciousness. Here there is a reciprocal action between an outside and an inside, and the cause of the phenomenon is precisely this reciprocal action. To ask whether the representation I have of a table—its form, its solidity, its color, weight, and so forth—agrees with the real thing is the same as to ask whether a tone is red, yellow, or blue. Things are determined by their properties, and the properties by reciprocal action with our organs of consciousness and with other things. Cinnabar is red, be it noted, for those who can distinguish colors, but black for the red-blind. Although the latter, according to the law of reciprocal action, have the same right in their judgment as the former, we nevertheless say in general: cinnabar is red; likewise we often ascribe to a thing a property as though it belonged to the thing in itself, although this property holds only for the thing's reciprocal action with other things, as when we say: lead is soluble, and tacitly understand: in nitric acid, not in sulfuric acid. The result is that our representations of things have only practical significance. Our designations, our words and expressions, are only symbols; out of these symbols a language can be formed, expressive of our observations, exact investigations, and scientific cognitions, but which has nothing, absolutely nothing, to do with the essence of things.

If this now is the final, decisive result of the inquiry, if the problem of knowledge is herewith once and for all solved—in principle, that is—if all further-reaching research will serve only for a further confirmation of the Kantian theory: then not only must the works of Fichte, Schelling, and Hegel be regarded as misguided, but every future philosophical attempt to illuminate the essence and ground of existence must be dismissed as barren and, for science, misleading. However the matter may stand, this much is certain, that the Kantian doctrine of knowledge has an ambiguity that must

³Handbuch der physiologischen Optik. Leipzig 1867. S. 442–flgd.

be drawn forth into the light. The fundamental question is: how can that which fills our forms of cognition with *real content* be so *absolutely heterogeneous* with these forms that the thing itself must remain entirely unknown to us?

Let us call the unknown X and confine ourselves to a definite object, for example a table. That we apprehend the table in space and ascribe to it a bounded extension, whereby it acquires its shape, is evident; but the pure intuition of space gives us no real table. The table is not a product of our own imagination; here is a something that acts upon our senses, notably upon sight and touch—this something is X . The table, the real phenomenon, thus comes about through two heterogeneous contributions, a subjective one from ourselves and an objective one from the thing in itself. We can symbolize it by an equation: $X + Y = P_{x,y}$, where X denotes the objective, Y the subjective, and $P_{x,y}$ a function of X and Y , the phenomenon. If we set $Y = 0$, then the subjective vanishes, and $X = P_x$, that in the phenomenon which is due to the objective alone, remains. That P_x cannot itself be a phenomenon, that subjectivity is required in order to make the thing into a phenomenon, Kant has excellently shown; but how this happens, or even the possibility that it can happen, he leaves standing in complete ambiguity. — How, then, does X actually stand in relation to $P_{x,y}$, the space filled by the table? One can conceive the matter in several ways. X may be assumed, without filling any space, to make an impression on the soul of such a character that the determinate space-filling corresponds exactly to the intensity of the impression. The real table is thus by no means a space filled by X , for the X -impression brings it about only that subjectivity, which itself fills the given space, must imagine that it is a real object that fills it. This assumption must strike us as unreasonable, especially when we consider that the table is not merely an object of sight, but also an object of touch. Everywhere that we touch the table's surface, we sense the reality. But the reality of every sensation derives, after all, from X -impressions; there must then be just as many different X -impressions as the table's surface has parts, and these impressions—whose difference here is a difference of place—must be arranged and distributed in exactly the same way as the parts of the surface, that is, arranged and distributed in space. Yet neither does this assumption satisfy, for it would follow that to the phenomenon of a square table there would correspond, if not indeed a square X ,

then at least X-impressions that fit exactly the square, to the phenomenon of a round table X-impressions that fit the round, and so forth. If one separates the impressions of X, which make the spatial determinations real, from X itself as that which is outside space, then the X existing outside space has, after all, nothing whatever to do with the real spatial phenomena; its significance for a filling of the intuition of space is reduced to nil.⁴

Similar difficulties present themselves when we consider the phenomenal changes that give the intuition of time real content. The substance-phenomenon shows us what *abides* in time, the accident-phenomena what *alternates* in time, and yet the substance must be characterized by the accidents, and the accidents by the substance. Now it is asked: is it one and the same X that determines the reality both of the substance-phenomenon and of the accident-phenomena, or are there here two kinds of X? If we assume the former, then we lay into X the very same characteristic difference as into the phenomena. As the X of substance it *abides* in time, as the X of the accidents it *alternates* in time; this will then, in other words, mean that the thing in itself, the unknown, is able to fill our intuition of time with real content only on the inviolable condition that it, both from the side of substance and from that of the accidents, enters into time, abides in time, and changes in time. But this assumption stands in manifest conflict with the Kantian presupposition. If we prefer the latter and posit one X for substance, another for the accidents, then the multiplication of X will also be carried further. It is then not enough to have a general X for substance in general; we must have a particular X for each particular substance, a sulfur-X for sulfur-substance, a carbon-X for carbon-substance, an iron-X for iron-substance, and so on; as regards the accidents, it will be doubtful how far we can make do with one X for each group of accidents, or whether just as many X's are needed as there are accidents in each group. The Kantian doubling—phenomenon and thing in itself—comes, in this light, strongly to recall the Platonic: the table and tableness, the horse and the horse-itself.

⁴If one assumes that X, in a certain negative way, reflects itself in its X-impressions that refer to the intuition of space, just as the X-impressions reflect themselves in the objects of experience, then one gets an X-phenomenon behind every experiential phenomenon; but since the X that stands behind the X-phenomenon must in turn reflect itself in an X-phenomenon that removes itself still further from the form of space, one gets X-phenomenon behind X-phenomenon ad infinitum before one reaches the last X, separated from space, the pure “Ding an sich”.

However one turns and twists it, the following question remains to be answered: Can X enter into changes or can it not? If it cannot, then it keeps itself quite rightly outside time, but then all phenomena of change become X-forsaken, unreal semblances. If X can take part in the changes and give them the stamp of experiential reality, then this reality-giving must also in one way or another itself enter into time-determinations and take part in time. To take up the X-impressions that determine the changes into the intuition of time, and yet to let X be outside the intuition of time, is an absurdity, for it is a contradiction.

The Kantian doctrine of knowledge impresses upon us that our concepts of the understanding have validity only in the determination of the objects of experience and find no application whatever to the thing in itself. But when the thing in itself falls outside all conceptual determinations, how then can it be determined? It is supposed not to be determinable by sensation, since it is strictly held outside space and time; it must therefore be determined by thought. Since now the understanding cannot possibly procure for itself any positive content other than what it receives from sensation, the consequence must surely be that the thing in itself can be determined only negatively. One would now suppose that the only determination that might be given of X would be this, that it excludes all determinations. It would then be just as indeterminate that it is as that it is not, just as indeterminate that it makes an impression on our senses as that it makes no impression, and so on. But in this supposition we are greatly disappointed. X becomes expressly determined by an act of the understanding; it becomes determined by a judgment, not by a negative, but by a positive judgment: *the thing in itself is*. Being, a concept of the understanding, is here, contrary to the theory's own prescription, applied to X. Being denotes reality, something positive; whence does the understanding get this positive? Not from sensation, for sensation gives only what can be apprehended in space and time. Nor from anything other than sensation, for here there is nothing else that can give the understanding the positive. So X must, then, be known indirectly by its effects, that is, by the sense-impressions of which it is the cause. But this assumption too the theory has excluded, for cause is a concept of the understanding just as much as effect. By determining the thing in itself as an unknown cause lying outside understanding and

sensation—a cause that is to be thought as objective and yet cannot be thought as objective, a cause that in its effects, for the sake of reality, must be sensed and yet cannot be sensed—Kant has, instead of showing the possibility of experience, on the contrary proved the *impossibility* of experience.

If there is no objective form at all that can belong to the thing in itself, then this unknown must necessarily dissolve into a hazy possibility, a ὕλη ἄμορφος, and lack all objective self-subsistence. It is then so far from the case that the in-itself indeterminate possibility can be said to determine the objective content of our subjective forms, that on the contrary it borrows its apparent forms of reality from us and only through this loan acquires the semblance of something objective. — Here, however, is a consideration that can be brought forward from the Kantian side. Doubtless we must ascribe objective forms to the thing in itself, insofar as we ascribe to it objective validity, but the point is that we do not know these objective forms at all. To be sure, they cannot be forms like ours; but who can prove that there are no other forms of existence than those that underlie our sensation and thought? Not to speak of the characteristic differences of our five senses—sight, hearing, smell, taste, and touch—both among themselves and among different individuals, or of the possibility that cognizing beings may have both more and sharper and finer senses than we, there is surely no human being who can vouch that our a priori intuitions and categories correspond even approximately to the objective form-determinations expressed in the thing itself. Is not the objectivity of space and time problematic? Must we not, even as regards objects of experience, make a distinction between the thing's concept and our imperfect, often faulty concept of the thing? — Here again we have the ambiguity.

It scarcely occurs to any reasonable person to deny the imperfection of our intuition of space when it comes to a clear and distinct apprehension of definite, many-sidedly combined and thereby involved relations in space. To construct in space is not exactly an easy matter. Should anyone doubt this, he need only make even a merely preliminary acquaintance with analytic geometry; he will then soon learn how easily a curve or a mathematical body, whose equation is known to him under certain conditions, can become unrecognizable either by a displacement of the coordinates' point of intersection or by the whole coordinate system's being altered. The more combined the figure

is, the more difficult are the special relations to see through: here, then, manifold doubts can arise about the objectivity of spatial relations in the particular. But it is one thing to concede the imperfection of the representations and sensations conditioned by the intuition of space, and another thing to deny objective validity to the a priori form-determinations of the intuition of space. If a cognizing being descended to us from higher regions and declared that it could distinguish millions of parts in the space we took to be filled by a single part, we should by no means contradict it; but if it moreover maintained that it could distinctly see the circle as a square and the square as a circle, should we then be convinced that its intuition of space was more objective than ours? If the stranger gave proofs that he could not merely sense the ether, but even count 733 trillion vibrations in one second, he would astonish us in the very highest degree; but if he then gave as the reason that he was able to apprehend the simultaneous as successive and the successive as simultaneous, should we then dare to conclude from this that his intuition of time came nearer to the objective than ours? Between space and not-space, time and not-time, no intermediate forms are possible. How many dimensions space may appear to the sensing being to have is not here the question; the question is of dimension and succession. By withdrawing itself from all determinations of space and time, of dimension and succession, the whole “objective, unknown world” must precisely become known to us as a single intensive point.⁵

In confirmation that our concepts of reason (ideas) find just as little application to anything objective in itself as our concepts of the understanding, Kant sets up four so-called cosmological antinomies, namely two mathematical and two dynamical. In this connection we confine ourselves to the mathematical ones. First antinomy. *Thesis*. The world has a beginning in time, and is, as regards space, enclosed within limits. *Antithesis*. The world has no beginning, and no limits in space; it is, in respect both of time and of space, infinite. Second antinomy. *Thesis*. Every composite substance consists of simple (uncomposite) parts, and there exists nowhere anything but the

⁵That the air-waves are heterogeneous with the tones and the ether-waves with the colors proves only that a cause in the objective can become unrecognizable by entering into reciprocal action with the subjective; but what is incomprehensible herein proves nothing either against the concept of cause or against the objective validity of time and space. Of the influence of our organization there will be speech later.

simple and that which is composed of it. *Antithesis*. No composite thing in the world consists of uncomposite parts, and there exists in general nothing simple in it. — Since the proof both for thesis and for antithesis in each of the antinomies must be granted the same validity, this mutual conflict of the transcendental ideas is supposed irrefutably to prove that we can just as little reach the objective by means of our reason as by the use of our understanding. Let us test the proofs. Does the thesis in the first antinomy stand in insoluble conflict with the antithesis? We cannot see that it does. If the world is from eternity, then there is, after all, no contradiction whatever in the fact that up to a given point of time an infinite series of successive world-states may have elapsed. To be sure, an infinite series cannot by any successive synthesis be completed in a finite time; it requires an infinite time in order to be completed. But from whatever finite point of time one looks back toward the infinitely distant beginning, one looks, after all, into an infinite time. If there is nothing contradictory in assuming an infinite series of represented terms, then there is nothing contradictory either in assuming an infinite series of real terms, provided the reality, be it noted, is presupposed to be from eternity. Why can the world not have begun in time? Because, says the antithesis, a time must then have gone before, hence an empty time; but in an empty time nothing can arise, since in no part of such a time is there any condition for a distinguishing of existence from non-being. But such an empty time is more imaginary than any imaginary magnitude otherwise is. With an imaginary magnitude, mathematically understood, one can nevertheless reckon; but an entirely empty time, a time in which there is no difference between the past, the present, and the future, is no time, and with no time one cannot reckon. As surely as the real world really has a beginning, its beginning must necessarily fall in a real time, and the real time begin with the real world. Since in this respect it makes no difference whether we push the beginning's point of time back half an eternity or a whole one, there is, as regards the world's beginning, no conflict between thesis and antithesis. — In considering the limitation and non-limitation of space we come to the same result. The real world is limited, for the outwardly real must at every moment have definite limits and to that extent be a finite. But the world in its finitude and limitation is also in real becoming, and can thus at every moment be on the point of overstepping every finite limit. It is the

real world that makes space objective and sets objective limits in space; cosmic space has no peculiar being outside the world. The antithetic is built on the impossibility of completing the successive synthesis of the terms in an infinite series, that is, on the impossibility of comprehending all parts of an infinite totality. But, we ask, will then a limited whole, which contains only 7 parts, be more real than a whole that contains 7 trillion parts, because the successive synthesis in the first case is easy for us, but in the last case impossible? Surely no one will maintain that. But if we may assume a totality with 7 trillion parts, a world-whole with 7 trillion firmaments, to be real, notwithstanding that the successive synthesis requires an enormously long time, how then can there be any contradiction in presupposing the reality of an infinite totality, because a successive synthesis (more correctly: coming-into-being) of its individual parts must have required an infinitely long time?

For the *Thesis* in the second antinomy it is adduced that nothing substantial could be given if no indivisible parts existed; the substantially composite must therefore consist of uncomposite parts. In support of the *Antithesis* it is adduced that no composition of substances is possible except in space. The substance existing in space must necessarily have substantial parts; but space has no substantial parts, it is a *totum*, no real *compositum*. The contradiction is now supposed to be: that composite substances cannot exist without simple substances, and that simple substances cannot exist in space. Instead of consisting of simple substances, the composite substance comes to consist of composite substances ad infinitum, and that is absurd. — This contradiction, however, is more imaginary than real. If simple substances and space are incompatible magnitudes, then not only experience but also mathematics is impossible, for then intuition, and with it sensation, is absolutely incompatible with thought. “It is here,” says Kant, “not enough, for the pure concept of the understanding of the composite, to find the concept of the simple; one must find the intuition of the simple that corresponds to the intuition of the composite, and this is, according to the laws of sensibility, hence also in the case of objects of sense, entirely impossible.” — This impossible, however, is not so evident as it might seem at first glance. A mathematical body, a cube for example, is an object of intuition; how does it stand here with the simple and the composite? The given cube can be intuited as a single existent, a continuum bounded

by 6 square faces; but it can also be regarded as a composite and resolved into elements. If it is denoted by an infinite summation of represented corporeality-elements $x^2 dx$, then the third part of the intuited cube is an integral, determined by finite limits, of these elements. The face can be resolved into face-elements $x dx$, the line into line-elements dx , and these again into elements of a higher order, and so forth. In relation to the body the corporeality-element is the simple, just as the face-element is the simple in relation to the face, and the line-element the simple in relation to the line. Thought and intuition are, as regards the mathematical body, agreed that the simple must be relative for the sake of the composite, and the composite relative for the sake of the simple, that therefore the fixing of an absolutely self-existent simple is not an idea of reason, but a fixed idea. Should not the same hold for the material body? It is supposed, according to Kant, to be an absurdity “besides the mathematical point, which is simple, but no part, only a limit in space, to think of physical points, which are indeed simple, but yet have the advantage, as parts of space, of filling it by their aggregation.” But the alleged absurdity will not become evident to us. Let us only put atoms and molecules instead of mathematical elements, and aggregations instead of infinite summations: the fundamental relation between the simple and the composite will nevertheless remain the same. That the finite discretion is a parceling-out, a breach of continuity, must be conceded. But even though the atoms are, in a real sense, ever so indivisible—indeed even if, what for other reasons is an absurdity, they are assumed to be absolute simple substances—the intuition of space can nevertheless have not the least to object against this. The atom’s substantial simplicity by no means stands in conflict with its mathematical divisibility. The extended-in-space simple substance has, to be sure, just as many substance-elements as the space it fills has space-elements, that is, it has infinitely many, for the discretion goes on ad infinitum. But since the infinite discretion, as is expressly seen from space, coincides with continuity, what can intuition object against the simple substance—a real continuum—filling space, the formal continuum? Since the parceling-out is presupposed, the finitude of aggregation steps in place of the infinitude of summation; but since the real distance between real parts precisely gives the form of space the stamp of reality, the aggregation must surely be an eloquent proof of the formal objectivity of space.

Kant is fully convinced of the insolubility of his antinomies, “denn für die Richtigkeit aller dieser Beweise verbürge ich mich⁶,” but the insolubility presupposed, what is thereby gained? “That we must not think the phenomena of the sense-world as things in themselves.” That must be conceded. But there follows yet something else from it, something that it is precarious to concede; for when it is expressly added that we must not think the fundamental principles for the connections of phenomena as valid for the things in themselves either, then the understanding is lost, then it grows dark before the eye of reason. If we could still stop at the preliminary result, that in all our cognizing we must hold to our experiences and leave undecided how the things themselves in the world unknown to us actually are constituted: that might pass. But the antinomies drive us to an extreme that must either turn into bottomless skepticism or awaken despair. We are to assume things in themselves which, although they condition our experiences, nevertheless exclude all conditions of experience, since neither space nor time, neither unity nor plurality, neither ground nor consequence, neither cause nor laws, neither whole nor parts, neither simplicity nor composition have the least significance for these in-themselves unsensible and unthinkable things. These are hard terms.

For the understanding of the conflict of the ideas of reason in the antinomies, Kant adduces the following: “Two mutually contradictory propositions cannot both be false, unless the concept that lies at the ground of them both is in itself contradictory; for example, the two propositions: a square circle is round, and a square circle is not round, are both false.” But when the human consciousness has only a choice between one of two: either to let the ideas of reason or the “things in themselves” be “square circles,” then it is at least excusable if it once more ventures to assert the right of reason by choosing the latter. This choice is characteristic of J. G. Fichte’s “Wissenschaftslehre”.

We can briefly denote the deviation from the Kantian standpoint by exchanging the symbol $X + Y = P_{x,y}$ for $XY = P$. That this must necessarily give the inquiry another direction and lead to an entirely different result is evident. When Y, the subjective, becomes nil, that is, when the cognizing subjectivity, the Ego, vanishes, the whole becomes nil: no indeterminable object, no self-existent X, remains. By establishing

⁶Prolegomena. Werk. 3ter Band. S. 264.

the reciprocal determination of subjective and objective, Ego and non-Ego, Fichte has introduced a great fundamental thought into the history of philosophy, a fundamental principle of such incisive significance that it can as little be excluded from the theory of knowledge as the law of gravity from physics. Although Ego and non-Ego mutually exclude one another, it is nevertheless self-evident that X, the non-Ego, can as little be ascribed any self-subsistence valid outside the Ego as it can merge together with the Ego itself. As real opposite to the Ego, the non-Ego must therefore be an element in the Ego's essence, a barrier that is indispensable for the Ego's self-development. Only by the thinking Ego's becoming conscious of its opposite, its barrier, as an unconscious presupposition that has proceeded from its own essence, does it become conscious of itself, and overcome the barrier theoretically. The objects of experience, the outward phenomena, present themselves immediately and with a necessity over which the Ego has no command, and thereby take on a stamp of outward reality; but that the Ego not only recognizes the forms and categories in which the objects present themselves as its own forms, but also recognizes the necessity with which they present themselves as a necessity of the Ego's own nature-ground, is, in the "Doctrine of Science," the solution of the problem of knowledge.

The critical illusion in Kant consists in this, that the unknown thing constantly appears as something self-subsistent in itself, objective, positive—indeed as the only unconditionally positive—notwithstanding that it shows itself from all sides that this positive can be determined only negatively. The negative is positive, the positive is negative; this contradiction, against which the critic defends himself with all his might, crops up everywhere and vexes the Critique. This illusion Fichte has seen through with clear consciousness, in that he has recognized the significance of the negative and ascribed to X an essential value as non-Ego.

But despite this unmistakable advance, the Fichtean solution is just as unsatisfactory as the Kantian. What from the objective side is impossible for Kant, namely to point out how the in-itself indeterminable X can fill the forms of cognition with an unsurveyable manifold of real determinations, the same is from the subjective side impossible for Fichte. As non-Ego, X is far too uniform to yield any explanatory ground sufficient for the diversity of the phenomena; a stone is a non-Ego, a plant a

non-Ego, an animal likewise: animals and plants have, in relation to the Ego, the same significance as minerals and stones. The subjective reflection of Ego and non-Ego consumes all objective relations between the phenomena among themselves. Kant does at least get a world of experience, even if on an ambiguous, self-dissolving foundation. Fichte, who removes the ambiguity of the foundation, does not get even so much; he gets only a subjectively necessary shadow-world of barriers and non-Ego, a world so empty that the nature-content vanishes, and the philosophical interest in the realities of experience is lost.

The Hegelian philosophy lets the problem of knowledge founder in the absolute knowing instead of being solved. The opposition of the cognizing subjectivity and the object of cognition, which is the bearer of the problem, dissolves into the dialectical unity of thinking and being that flows through the Logic and issues in the Idea. In the Idea, the Absolute, subjectivity is sublated, that is, it is transformed into a co-determination, a moment, even if a moment of totality; and the same holds of objectivity, though with a noticeable preponderance over the subjective. Instead of an intuiting, thinking self-being that has the concept for its content and the concept's reality for its object, we get in Hegel a concept that comprehends itself, an Idea which, after having given itself subjectivity in the form of reflection, again sublates this its subjectivity and translates itself into the form of immediacy as objectivity in existing objects. The concept, in absolute unity with its content *the Idea*, cannot possibly maintain itself in two opposite forms at once; when the Absolute is posited as subjective Idea in the form of subjectivity, that is, of reflection, the objective is reduced to a moment and has vanished; when the Absolute is posited as objective Idea in the form of objectivity, that is, of immediacy, subjectivity has vanished: it must then comprehend itself. But when the objective is to be able to comprehend itself just as well as the subjective, then the self-comprehending concept is incomprehensible. If the absolute Idea is to be the concluding unity of subjective and objective Idea, then it must either assume a form which, in being neither subjective nor objective, raises it above the extremes, or it must be one of those two opposite forms in which it holds the extremes conjoined. The former is, from Hegel's standpoint, inadmissible; for Schelling's indifference of subjective and objective is only an abstract presupposition,

a non-ground, which stands far below the Ideas, and an over-subjective or an over-objective has no warrant in “the absolute knowing.” As regards the latter, we must then choose either the subjective or the objective as the original form of the absolute unity; but the Hegelian philosophy makes the choice impossible for us. If one compares the Logic with the philosophy of nature, it appears as though the nature-Idea, the Idea in the objective form of immediacy, were the derived, and the Logic’s Idea, the Idea in the subjectively reflected form, the original. But by comparing the philosophy of nature with the philosophy of spirit we are convinced that the matter stands the reverse; for logic in logical reflection presupposes spirit. There can be no logical reflection where there is no spirit; but nature is the presupposition of spirit, just as immediacy is the presupposition of reflection. Nature is spirit’s “An sich,” and nature is the objective; it is therefore the objective concept that—in an incomprehensible way!—comprehends the subjective. That Hegel, by the immanent dialectic of the ideal form-determinations, takes a giant step forward, that by going further than Schelling he gets negativity developed by another measure and in a quite different depth than either Kant or Fichte, must be conceded; but the Absolute itself he does not get cleared up. Despite all the talk of the self-thinking thinking, the absolutely self-knowing spirit, it is impossible to learn what the knowing itself, the absolutely knowing, is—whether it is absolutely subjective or absolutely objective, whether it is a self or a self-less process or perhaps neither of the two. It is a self-comprehending concept that is to clear up everything and bring the last remnant of the unknown to vanish; but far from having eliminated X, the incomprehensibly self-comprehending has transformed the Absolute itself into an X, an impenetrable riddle that can fittingly be denoted by an enigmatic symbol: $XY = X_{x,y}$.

If the problem of knowledge is to be solved, the following fundamental conditions must inviolably be held fast:

- 1) *There must be an insoluble opposition of subjective and objective, in which subjectivity itself, with its a priori forms, is the overreaching unity.*
- 2) *Cognition must rest upon so thoroughgoing a reciprocal determination of the subjective and the objective that no object can either be or be thought to be without a corresponding objectivization.*

- 3) *That imperfection of objectivization which has its ground in the independence of the existing objects from organically conditioned subjects must be capable of being remedied by subjective equivalents of ontological objectivization.*

Against Fichte and Hegel, Kant is, as regards the first fundamental thought, unmistakably right when he holds fast the opposition between the cognizing subject and the object of cognition, just as he also—from the side of finitude—is right in presupposing an unknown, a thing in itself, that does not resolve into our cognition. But in the manner in which he determines the thing in itself he is grossly wrong; for it is not by excluding the a priori subjective form-determinations that the thing withdraws itself from knowability⁷, but by its apprehension being modified according to the subjective peculiarity of the senses and of the sensing beings. The unknown thing that is the object of sensation is a thing with sensible properties just as well as the experiential phenomenon that comes to our consciousness by way of sensation. In sense-systems of different order, A, B, C, and so on, the same unknown X with its properties must necessarily present itself in different phenomena. In the A-system the properties $x_1, x_2, x_3, \dots$ will present themselves as $a_1, a_2, a_3, \dots$, in the B-system as $b_1, b_2, b_3, \dots$, and thus in the first case give the experiential object P_a , in the last case P_b . The cognizing beings have in the one system just as much right as those in the other. But when the cognizing beings must all concede that the thing itself falls outside their

⁷The more recent Critique has, however, gone briskly forward, in that it has extended the influence of “our organization” to categories such as unity and plurality, substance and accident, subject and predicate, and so on. We are, it is said, naturally compelled to apply such categories on account of the peculiar organization of our understanding; but it does not yet follow from this that they are in themselves immutable. Enigmatic Critique! That the understanding must not be conceived as a faculty by itself over against the other faculties of the soul, that its activity must be dependent on organic dispositions, can be seen from differing endowment; the understanding of the individual may be disposed to one kind of intellectual activity without being in the same degree disposed to another. Nor can it be denied that a one-sided direction of the understanding may mislead one into fixing fundamental concepts as exclusively a priori which yet are demonstrably not so; one may think of the Pythagoreans’ philosophical conception of the decadic system, for example. But such missteps are, after all, to be corrected by the understanding itself according to the understanding’s laws. Those critics, on the other hand, who give themselves the air of being able to conceive—not merely an understanding infinitely higher than the human, for that we can all do—no, an understanding that annuls the difference between unity and manifold, cause and effect, subject and predicate, must assuredly distinguish themselves by a quite peculiar organization. “Metaphysics” they might now easily abolish; but how does it go with the understanding? In order to conceive an understanding that is absolutely heterogeneous with the human understanding, the human being must, after all, take leave of his understanding.

cognition, on what then does the truth of cognition rest? The answer to this question leads us to the second fundamental condition.

If the object in itself, with its properties, its concrete determinations, could really stand independently outside all objectivization, and if the objective thus standing were the really true, then the cognition of truth would be impossible. But by working through the relation between Ego and non-Ego, Fichte has strikingly proved that the objective, far from being independent, is dependent on and determined by subjectivity. The exaggeration with which he asserts the pure Ego's original self-limitation, and the energy with which it itself posits its objects, furnishes a most necessary counterweight against the vulgar assumption that objectivization does not really concern the objects, but that it becomes subjectivity's own affair whether it objectivizes truly or falsely. When we now concede to Fichte that every real object must be a necessary product of an objectivizing subjectivity, but cannot possibly concede to him that the objects really are in themselves as we objectivize them to ourselves, or that our human objectivization should be able to give the things existence, then we resort to the third fundamental condition, in order to discover how the imperfection of the finite objectivization is to be remedied.

The universally valid ground of cognition coincides with the ontological ground of objectivization. When someone, for example, propounds the hypothesis of the rotating primordial vapor out of which our planetary system is supposed to have developed, he certainly does not assume that that vapor was an object of experience for human sensation, any more than his opinion is that what was then "a thing in itself" has since, through our experiences, been transformed into vapor. Nor does he assume either that the primordial vapor existed in our subjective intuition of space and rotated in our subjective intuition of time, nor that it is we who with a priori necessity have prescribed to nature the laws according to which the whole development has taken place. No, he rather assumes that all of it—the space, the time, the vapor, the motion—was objective without any objectivization whatever. Since it is now proved that the last assumption is just as meaningless as the first, what follows from this? That here in silence there must have been slipped in a subjective equivalent of ontological objectivization! Hypothetically this is expressed thus: if we had been present and

been able to survey the whole, then the matter must necessarily have appeared as the description runs. Thus: every time our limited subjectivity goes beyond its own bounds of experience, it becomes, for the sake of the objective, compelled to presuppose an intuiting that is not our intuiting, a seeing that is not our seeing, a thinking that is not our thinking, an objectivization that is not our objectivization; it becomes, in short, compelled to presuppose an ontologically objectivizing subjectivity.

From the ontological fundamental law of objectivization, symbolized by $XY = O$, where O denotes the object, it follows: that every objective moment must necessarily presuppose a corresponding subjective one, since $Y = 0$ gives $O = 0$, and that conversely every subjective moment in a real objectivization must be determined by a corresponding objective one, since $X = 0$ gives $O = 0$. Subjective and objective are, in the ontological sense, correlative concepts, but not coordinate: the objectivizing subjectivity is, as the overreaching unity of the opposition, a *dignitate prius*.

From the fundamental law it follows further that the truth of cognition rests neither on the objective by itself nor on the subjective by itself, but on the reciprocal determination of both. Let there be thousands, indeed millions, of diversely constituted sense-systems in the universe, still the a priori forms of cognition are the subjective fundamental forms of universal reason, and universal reason is common to all cognizing beings. The cognizing beings that, with the same sense-system, come under the same order must see that the concrete objectivization conditioned by sensation has all the truth it can and should have, when the reciprocal action between the subjective and the objective is precisely determined for the order in question. The dissimilar sense-systems are just as little able to awaken doubt about the universal validity in the peculiarity of objectivization as the red-blind man, despite the truth of his objectivization, is able to awaken doubt about the difference of colors among those who have color-sense. The truth is that the reciprocal action between subjective and objective must be different for subjectivities of different order; but *the reciprocal action itself is the truth*. To assume an X standing outside the reciprocal action, unobjectivized, for the really true, is a dream, an imagining; outside the reciprocal action there is no truth, for outside the reciprocal action there is, ontologically understood, nothing at all.

II. The Problem of Reality

While Hegelianism has sought to transform the world of realities into a system of metaphysical concepts, Positivism has, for a change, thrown all metaphysical ballast overboard, in order to hold exclusively to realities and facts. It is, as is well known, not the realities that conform to our concepts, but conversely our concepts that must conform to the realities; the wisest thing philosophy can do is therefore to give up the a priori problems, abandon its old leaky vessel, go on board the steamer of physics as a passenger, and assume the title of Positivism. In justification of so important a step, the school's celebrated founder, Auguste Comte⁸, has pointed out three stages of development (*trois états*) which the human mind must necessarily pass through on its way to the cognition of truth, *the theological, the metaphysical, and the scientific*. At the theological stage one seeks the cause of the phenomena in a supernatural will and lets the arbitrariness of the supernatural will determine the course of things without regard to fixed laws. At the metaphysical stage the arbitrariness disappears and gives place to such supersensible, self-valid entities as the Absolute, Substance, the Cause, the Idea, and so on. This intermediate stage has been necessary as a transitional step from the theological to the scientific⁹; but in itself the metaphysical standpoint is barren, as can be seen particularly from the endless, resultless disputes into which it dissolves. The positive philosophy, which stands at the scientific stage, now characterizes itself by this, that it regards the phenomena as subject to unchangeable laws, seeks to reduce these laws to the smallest possible number of fundamental laws, and considers every attempt to penetrate either to the first causes or to the so-called final causes as utopian and meaningless¹⁰.

⁸*Cours de Philosophie Positive; Tome 1mier, Paris 1830. 1miere leçon.*

⁹*La théologie et la physique sont si profondément incompatibles, leurs conceptions ont un caractère si radicalement opposé, qu'avant de renoncer aux unes pour employer exclusivement les autres, l'intelligence humaine a dû se servir de conceptions intermédiaires, d'un caractère bâtard, propres, par cela même, à opérer graduellement la transition. Anfrt. Skr. S. 13.*

¹⁰*Nous voyons, que le caractère fondamental de la philosophie positive est de regarder tous les phénomènes comme assujétis à des lois naturelles invariables, dont la découverte précise et la réduction au moindre nombre possible sont le but de tous nos efforts, en considérant comme absolument inaccessible et vide de sens pour nous la recherche de ce qu'on appelle les causes, soit premières, soit finales. Anfr. Skr. S. 14. Further, S. 16: La preuve manifeste de l'impossibilité d'obtenir de telles solutions, c'est que, toutes les fois qu'on a cherché à dire à ce sujet quelque chose de vraiment rationnel, les plus grands esprits n'ont pu que définir*

To exclude metaphysics is fully justified when by the word metaphysics one denotes a science that puts imagination in the place of experience in order to discover the essences and *qualitates occultæ* of which real things must absolutely consist, unconcerned whether it agrees with reality or not. But against so superficial a conception of the concept of metaphysics one must protest in the name of science. Hegel's "Wissenschaft der Logik" is essentially metaphysics. Whatever imperfections may be pointed out in this Logic, one should nevertheless not accuse the author of fetching his concepts from the world of imagination. The concepts are so inherent in the things that no existing thing can escape corresponding to its concept. That "cultivation and discipline" of consciousness¹¹ which Hegel demands on behalf of Logic he can with full right demand on behalf of all the sciences. — The relation between physics and metaphysics we may determine thus: physics forms its concepts according to the observed facts, metaphysics develops its concepts out of the conditions necessary for all being and existence. To deduce the concretions of the concepts of existence from pure thought is impossible; but to give an account of empirical phenomena without going back to the a priori concepts is also impossible. Gold, silver, iron are called partly different *things*, partly different *substances*; what use is it now to denote reality, the given fact, now by the word *thing*, now again by the word *substance*, when one is not in agreement with oneself as to wherein the designation substance differs from the designation thing? In science one must after all know what one is oneself saying. In order to be a *definite thing*, the phenomenon must absolutely be a *thing*; in order to be a *definite substance*, it must be a *substance*. On this point physics has the advantage of consulting metaphysics. In metaphysics, the objective logic, it is not only made evident that the thing must necessarily reflect itself in the properties, and the properties in the thing, the substance in the accidents and the accidents in the substance; but it is also made evident wherein the reflection consists, and how

ces deux principes — l'attraction et la pesanteur — l'un par l'autre, en disant, pour l'attraction, qu'elle n'est autre chose qu'une pesanteur universelle, et ensuite, pour la pesanteur, qu'elle consiste simplement dans l'attraction terrestre.

¹¹"Das System der Logik ist das Reich der Schatten, die Welt der einfachen Wesenheiten, von aller sinnlichen Konkretion befreit. Das Studium dieser Wissenschaft, der Aufenthalt und die Arbeit in diesem Schattenreich ist die absolute Bildung und Zucht des Bewusstseyns." Hegel. Wissenschaft der Logik. Berlin 1833. Einleitung. S. 47.

different it is in the case of the thing and in that of the substance.

From this standpoint it will be instructive to see two such strong thinkers as Comte and Hegel try their strength with one another. Comte maintains that there is no Absolute; and he is right insofar as he looks only at existence and the existing. In the world of facts the one term stands against the other, the one atom exists beside the other. Everything is parceling-out, everything is relation. Hegel maintains that the only thing that in truth is, is the Absolute; and he is right insofar as he looks at the original unity of being with universal thought. The relative is not merely relative in relation to another relative; but all relations and relative terms have their subsistence in an encompassing whole. If the encompassing whole is itself relative, it must necessarily have its subsistence in relation to the relative term. But in this thoroughgoing relation it then relates, through all relativities, to itself, and precisely thereby comes to subsist as the Absolute. Comte maintains that all that is logical is subjective; and he is right insofar as he thinks only of formal logic, for formal logic with its abstractions is undeniably subjective. Hegel maintains that the logical is essentially objective; and he is right insofar as he starts from the essential unity of thinking and being. The determination of thought to which no being corresponds is just as empty as the determination of being to which no thought corresponds.

Comte assumes that thing and reality can very well be determined in themselves and present themselves to us without any objectively determining concept; but here he is wrong. We abstract, as it is said, our concepts from the things; but to abstract concepts from things in which there are no concepts is just as impossible as to pluck hairs from the bald man. Hegel assumes that the objective concepts in their immediacy are themselves things, and that it must therefore be possible to deduce existing facts from logical universal concepts; but here he is wrong. How unhappily every attempt at a construing of real things *a priori* must turn out, his philosophy of nature has more than sufficiently demonstrated.

Comte teaches that reality is reality, but not concept; Hegel teaches that the concept as concept is reality: in the clearly expressed opposition between Positivism and absolute Idealism the *problem of reality* can properly first be said to arise.

The problem is: that thing and concept must be assumed both to be the same and

yet not the same.

That thing and concept must, in an essential sense, be the same can easily be seen. Take whatever thing or existing object you will, and you will convince yourself that the sum of all determinations—be they material or ideal, sensible or unsensible—must, since the determinations characterize the object and make the thing what it is, necessarily belong to the object's concept. In its sum of determinations the object subsists; with a change in the determinations the object changes; with the dissolution of the determinations the object disappears. When it nevertheless seems as though there lay something more in the object itself than in its concept, this derives simply from a confusion of the object's concept with our concept of the object; for our concepts of concrete objects are far from being exhaustive. That gold's color, malleability, specific gravity, form of crystallization, slight affinity for oxygen, and so on, are properties that characterize this metal and to that extent belong to the concept of gold, there is surely no one who will deny. When we must nevertheless admit that we have only an imperfect concept of gold itself, the reason for this is easy to explain. We are, after all, still far from knowing all of gold's properties, and even if we knew them from experience, we could still not boast of knowing gold's substance so long as we are not able to derive the properties from one another mutually or from the common unity in which they, as accidents, have their subsistence. To be yellow, to be malleable, to crystallize in octahedra, to have affinity for chlorine, cyanogen, and so on, are in reality such dissimilar determinations that no mortal is able either to point out their law-determined dependence on one another mutually or to discover the real unity from which they all with necessity proceed. And yet physics must concede that color, malleability, crystal-form are just as much functions of the gold-atoms' quality and arrangement as gold's unequal affinity for chlorine and oxygen; in other words: physics' conception of the laws is not limited to certain relations between thing and thing in outward generality; but every thing with its properties, every whole with its parts, every substance with its accidents, every body with its molecular structure expresses a system of law-determinations in which term and relation reflect one another. Even the smallest parts can, in the all-sided reciprocal action, just as little fall outside the reflection comprehending its moments as they can fall outside the laws.

Since now all determinations, both of the particular terms and of the terms' mutual relations, enter as real moments into the determining reflection, and the totality of the reflected determinations is one with the concept, it follows from this that thing and concept must be the same.

And yet concept and thing are by no means the same; they are, on the contrary, completely opposed to one another. What a difference between the concept of gold and the existing gold! The existing is immediately a fact, an object of experience; but the concept as concept tolerates no object of experience, no residues of immediacy, whether of sense-impressions or of images or of representations: everything must be dissolved, melted, purified in that fire of negativity which gives the concept its ideality's unsensibleness and logical distinctiveness. From this standpoint Comte undeniably has ground to make a divorce between concept and fact; for what holds of the fact does not hold of the concept. One can crush a stone, but not the stone's concept; one can boil a plant, but not the plant's concept; one can shoot a bird, but not the bird's concept; the concept can be thought, and one can think *of* the thing, *about* the thing, but the thing as thing cannot be thought. The concept, the universal, can be expressed in words, but the thing's individual determinateness must be pointed at as at a This and This.

The immediacy that distinguishes thing from concept cannot be logical; for even though the logical can point beyond itself, this always happens within the sphere of logic: Hegel's Logic is an eloquent example of this. Nor can the immediacy be illogical; if the object-determinations were illogical and stood in contradiction with the logical, the object would either be concept-less or stand in contradiction with its concept. Nor can the immediate in the object be something that is added or joined from outside to the logical, as when in certain logics a distinction is made between the object itself and the concept expressed in the object. What indeed should this something be? The material, matter? But if matter with all its determinations falls outside the concept, how then can the concept be expressed in the material object?

When now the sought immediacy can be neither logical nor illogical nor joined to the logical in an outward manner, then it must surely be the not-logical, which the logical needs, a necessary complement with which it is saturated, in that it disappears;

this complement is the antilogical.

If we seek the logical root from which the antilogical springs, we find it in the category of power. Power in its immediacy is the expression of reality, and the expression of reality's immediacy is again the antilogical. The reason we regard the objects as realities and ascribe to them an immediate, objective self-subsistence is precisely the impression of the power with which they, each singly, come to meet us. The objects of experience appear in this light like great and small potentates, who maintain their place in proportion to the power they have; only that, for the sake of immediacy, we must add that, without all logical reflecting, they are what they have, and have what they are. In apprehending facts, things, and realities from this standpoint, we have, in consequence of the logical, come out beyond the logical. The opposition of thing and concept is so striking that, when the thing is posited, the concept has disappeared, and when the concept is posited, the thing has disappeared.

If we now go back to the fundamental law of ontological objectivization, which was treated under the problem of knowledge, then it becomes possible for us to point out the ground both of Positivism's and of Hegelianism's one-sidedness. In that the Positivists immediately make straight for facts and real objects, they entirely forget to examine the relation between object and objectivization. The law says: as the object is, its objectivization must be; as the objectivization is, the objectivizing subjectivity must be. Since the adherents of the positive philosophy quite overlook this law, they cannot, with all their interest in the exact investigation of reality, of course get their eyes open either for objectivization in power or for the objective real-concepts by which the realities are *a priori* determined. They are zealous for the cognition of the unchangeable laws, without a suspicion that the unchangeableness of the laws has its ground precisely in the system of real-concepts. The best proof of this is the fact that Stuart Mill, whose inductive logic has set empirical induction in the clearest light, himself admits that the laws do not demonstrably belong to the essence of things, that one may very well imagine regions of the heavens where "events follow one another by pure chance without any fixed law." Just as little have the Hegelians, despite their absorption in the dialectic of the objective concepts, been attentive to the fundamental law of objectivization. They have categories such as

“Becoming,” “Appearing,” “Mediation,” “Passing-over into its opposite,” and the like; but the category of objectivization is not to be found in the whole system. Had Hegel but once fixed his sharp, penetrating gaze on the problem of objectivization, then we should surely have got another explanation of the transition from the subjective to the objective than is the case in that part of his *Logic* which he calls the subjective¹². If it is already from a logical standpoint evident that the object’s concept cannot possibly objectivize itself, that self-objectivization in the objectivization of another is and must be subjectivity’s ineffaceable characteristic mark, then it follows irrefutably from this that a subjectivity which in thinking, reflecting, and comprehending holds itself strictly within the boundary of the logical will never be able to carry it further than to

^{12a}“Der Schluss ist *Vermittlung*, der vollständige Begriff in seinem *Gesetztseyn*. Seine Bewegung ist das Aufheben dieser *Vermittlung*, in welcher nichts an und für sich, sondern jedes nur vermittelt eines Andern ist. Das Resultat ist daher eine *Unmittelbarkeit*, die durch *Aufheben der Vermittlung* hervorgegangen, ein *Seyn*, das eben so sehr identisch mit der *Vermittlung* und der Begriff ist, der aus und in seinem *Andersseyn* sich selbst hergestellt hat. Dieses *Seyn* ist daher eine *Sache, die an und für sich ist*, — die *Objektivität*.” Hegel. *Die subjective Logik*. Berlin 1834. S. 170–171. When the subjective movement through mediation has reached objectivity, and the immediate totality of being-determinations stands before the logical consciousness as a factually given, it shows itself what kind of subjectivity it was that comprehendingly found the object. It is by no means the substance comprehended in the causal relation that has transformed itself into judging, inferring, mediating subjectivity and thereby produced the objective; it is quite simply a human reflecting subjectivity, which has assured itself that there must be concept in the world of objects, and now — without in the least seeing how this concept has become object, contenting itself with the assurance that the object is a concept — regards it from the outside, and seeks therein to find and recognize the formal determinations that the subjective logic has developed. Here there can be no question of ontological objectivization. — “Darum ist das Erklären der Bestimmung eines Objekts, und das zu diesem Behufe gemachte Fortgehen dieser Vorstellung nur ein *leeres Wort*, weil in dem andern Objekt, zu dem sie fortgeht, keine Selbstbestimmung liegt. Indem nun die Bestimmtheit *eines Objekts in einem andern liegt*, so ist keine bestimmte Verschiedenheit zwischen ihnen vorhanden; die Bestimmtheit ist nur *doppelt*, einmal an dem einen, dann an dem andern Objekt, ein schlechthin nur *Identisches*, und die Erklärung oder das Begreifen insofern *tautologisch*. Diese Tautologie ist das äusserliche, leere Hin- und Hergehen; da die Bestimmtheit von den dagegen gleichgültigen Objekten keine eigenthümliche Unterschiedenheit erhält, und deswegen nur identisch ist, ist nur *Eine* Bestimmtheit vorhanden; und dass sie *doppelt* sey, drückt eben diese Aeusserlichkeit und Nichtigkeit eines Unterschiedes aus. Aber zugleich sind die Objekte *selbstständig* gegen einander; sie bleiben sich darum in jener Identität schlechthin *äusserlich*.” *Die subjektive Logik*. S. 183–184. Consistently, the development of the concept under this presupposition ought to have gone the way of experience, to have penetrated the method of natural science and thereby secured for itself the concepts’ expression in facts; but instead the illusion of the self-comprehending concept giving itself objectivity gained the upper hand to such a degree that one, after having intoxicated oneself in the dialectic of the immanent method, has now quite given up the dialectical — although dialectic is precisely a thoroughgoing critique of ideality — and is close to forgetting “die absolute Bildung und Zucht des Bewusstseyns,” which philosophy can never dispense with, and which for so essential a part is nevertheless owing to the great master.

a logical objectivization of logical objects.

In the real world the objects are not logical; they are real, immediate, antilogical: their self-subsistence consists in immediate power, their mutual relations are power-relations. What now lies in this? As the objects are, the objectivization must be: power-objects must be objectivized in power; further: as the objectivization is, the objectivizing subjectivity must be: only an absolutely powerful subjectivity is able to let realities proceed from their possibilities and bear a world of objects that really stands by power. In the objects power is immediate as power in another; in the objectivizing subjectivity power is reflected as self-power. Self-power, the subjective power, is ideal and logical; the object-power, the objective power, power in another, is real and antilogical. The opposition of ideal and real power is the strongest, deepest opposition that can be thought. Here is a real dualism; but the dualism is grounded in original unity, for the absolute self-power has the opposition within itself and masters its opposition.

The age-old question of the origin of the world-matter thereby comes under a new light. Aristotle lets, as is well known, matter and form be equally eternal, both belonging to that cycle of movements in which possibility alternates with actuality, and actuality with possibility; matter is the possibility, form the actuality. But this explanation is not appreciably better than the more recent Materialists' assurance that matter and force are equally eternal. What indeed is it, to be eternal, if it is not to be the absolutely original? Absolutely original is, after all, only that which has the ground of its origin in itself. But how is a being to be able to have the ground of its origin in itself, if it does not at the same time have a ground of origin for something other than itself? Aristotle describes the first mover, which is not moved, the Godhead, as the being that does nothing other than eternally to think the thinking of thinking (αὐτὸν ἄρα νοεῖ ... καὶ ἔστιν ἡ νόησις νοήσεως νόησις)¹³ and which, in order not to stain its perfection with anything imperfect, must exclude the possibility of being-other. But to exclude the possibility of being-other is to exclude matter. That such a conception of the original cannot withstand a critical test is easy to point out. If the eternal being is to think itself, then this must necessarily happen by a movement

¹³Translator's note: the Greek (Aristotle, *Metaphysics* XII.9) reads roughly "it thinks, then, itself... and its thinking is a thinking of thinking."

of thought in which it holds itself fast by distinguishing itself from something other than itself; merely in order to think itself it needs an other. If, moreover, its thinking is to be one with an active, real being, then this active self-being must necessarily contain the possibility of being-other; but the possibility of being-other is precisely matter. An eternal self-being without matter-being, an eternal matter-being without self-being, are hollow abstractions. The opposition of intellectual and real shows itself here in its first ontological shade. One may now, with Spinoza, attempt to lay the all-reality into the being's universal unity, conceive the self-being as the infinite substance (*causa sui*) with opposite attributes, thought for the ideal and extension for the material, and reduce the finite things to modifications, limitations, negations of the infinite: it does not help. The abstraction sucks the blood of the substantial, so that there remains neither self-being nor other-being, neither ideality nor reality, that has any self-subsistence to show. The positivistic way out, to draw a line through metaphysics and hold to the realities of experience, is, as shown above, impassable; unless the decisive step is to be taken in all thoughtlessness. For as regards the way out of thoughtlessness, there holds of metaphysics what Hegel somewhere says of reason: the best way in which one gets rid of it is: not to get involved with it at all.

If one is to hold fast reality without giving up thought, then the ontological fundamental law holds, that the subjective, self-reflected ideal must have the original power in order that the objective, the immediately real, may have the derived. An equalization of the mighty opposition between self-power and power in another cannot take place by subtraction and addition. One does not increase self-power by drawing something from power in another; nor can one strengthen the real by weakening or diminishing the ideal. On the contrary! The greater the reality the objective has, the mightier must the ideality be with which it is posited and determined. The objective world of facts, of realities, is, in the scientific sense, the strongest expression of the ideal power with which the ontologically universal self-being masters and comprehends itself in all and all in itself. All scientific truth stands and falls with the fundamental principle that the finite subjectivity, which objectivizes in impotence, must everywhere have its ontological equivalent in an infinite one, which objectivizes in omnipotence.

The transition from ideal to real, from concept to thing, corresponding to ob-

jectivization, has no intermediate determinations and can have none. How indeed should these intermediate determinations be constituted? Logical they cannot be, for one may enrich a concept with as many logical determinations as one will, it still remains, as concept, within the logical. Antilogical they cannot be either, for the antilogical enters only when the transition has taken place. The transition must then be a power-movement, a conversion of power's ideality into real power, a leap by which nothing is leapt over, a *logical-antilogical outburst of power*. Such an outburst of power is originally one with the transition from *possibility to actuality*—understood, be it noted, in such a way that the possibility lies in the concept, hence in the logical—*potentia ab posse*¹⁴—the actuality in the antilogical reality, hence outside the logical. Let us see it in some examples. He who is to walk with a light in a powder-magazine must be careful: he has an explosion to fear. That the explosion is a transition from possibility to actuality, an outburst of power, surely no one will deny. So long as the powder remains in actuality, in antilogical reality—saltpetre, charcoal, and sulfur in mechanical mixture—the explosion is only a possibility that lies hidden in the powder's actuality; but when the explosion becomes actual, the powder becomes unactual. The oxygen from the sulfate of potash unites with the carbon into carbonic acid, the nitrogen develops in gaseous form, the saltpetre's potassium forms with the sulfur potassium sulfide—in short: the actual powder disappears; but the powder's concept, the real-concept powder, remains behind in the elements as possibility. The *sudden* is here only a sensible indication of the *qualitative*. The possibility of hydrogen chloride, a mixture of chlorine and hydrogen, can, by being placed in sunlight, show a sudden turn into actuality. But the same transition can also take place slowly, when the mixture stands in daylight; the transition can then be regarded as a successive summation of manifold small, indeed infinitely small, outbursts. The outburst rests on the qualitative: either the hydrogen chloride's possibility or its actuality, in other words: either the ideal or the real, either possibility or actuality, either concept or reality; an intermediate there is not. To wish to condense the concepts into realities or sublime the realities into concepts is a speculative bungling, in equal degree contrary to experience and sound logic.

¹⁴Translator's note: the print here reads "polentia af posse" (in roman), evidently a misprint for *potentia ab posse*, "potency from being-able-to-be."

The whole real world rests upon an original outburst of power. If one rejects the unity-power, the all-comprehending self-power, then the system of real-concepts disappears and with it all the possibilities of reason. If one assumes the self-power, then there follows with necessity, as lies in its concept and comprehension in power, an outburst of antilogical realities. The characteristic mark of the outburst's antilogical reality is, seen from all sides, *otherness*. The elements of actuality have a double-sided stamp of otherness. That they are the other of self-power is seen from this, that they constitute the real manifold, the swarm of atoms, the parceling-out of immediate power through which the mighty unity confirms itself. That there really is reality in this otherness is seen from this, that there are objective relations, that the elements relate to one another as other by other to other ad infinitum. We see it in the relation between matter and force. Matter with its atoms is a striking expression of power in another. It appears, on a superficial view, as though the atoms' existence in space were only a collective coexistence with no other relation than that which lies in the spatial relations. Consistently the Positivists must, presumably, acquiesce in this assertion. By empirical induction one is supposed to be able to convince oneself that the one atom-group follows upon the other—usually!—according to a definite law. By taking motion as a fact and appealing to the law, one gets free of force; that is, force is transformed into a mathematical symbol, for example into the second differential coefficient in accelerated motion. At this standpoint, however, Materialism cannot maintain itself. The active relations between atoms and atom-groups are too conspicuous for one to be able to escape the impression of a real attraction and repulsion. The active relations now acquire a gleam of reflection, and the reality of reflection makes itself known in force. Then it is said that force, for example the force of gravity, is a property of matter. But when force, the reflected-in-relation, is the active, then it must surely also be the really actual, and what then is matter? One does not rightly know whether it is matter that acts by virtue of its property, force, or whether force is perhaps something particular, a kind of reflected reality that adheres to matter, the immediate reality. The last assumption is not satisfactory; so one goes further, draws the immediate reality under reflection, makes matter itself into a phenomenon of forces, sublimates it into forces and force-points. But—*naturam furca expelles*—the antilogical immediacy

asserts its right; one is nevertheless compelled to recognize a side of force that is *opposite* to force, and to grant matter, the immediate, self-less otherness, its inertia.

The unity-expression for matter and force is power in another, understood in such a way that matter, the immediate in power, yields the existing terms, and that force is reflected in the active relations. In matter the concept founders, the existing stands in the concept's place; but that the antilogical in existing matter is nevertheless logically determined by its real-concept can be expressly known from force. That two masses existing in space can attract one another at a distance is certainly incomprehensible when one throws the concept away; the representation of an attractive force adhering to matter gives no explanation. Only when one takes the real-concept along does the matter become intelligible. The existing masses are only one-sided expressions of power in another. One supposes that one has reality's complete expression in each of the masses by itself, and is astonished that two such realities, which, as it seems, need nothing but the space they each fill, can have anything to do with one another. That is an illusion. To existing terms' actuality there belong active relations; the attractive force, an expression of active relation, belongs inseparably in the real-concept in which the masses' reality is originally grounded.

Let us pause a moment to hear an objection. From the standpoint of physics, and then especially of Positivism, it must surely hold that attraction is a fact, and that the discovery of the law of attraction, independent of any analysis of metaphysical real-concepts, is owing solely to empirical observation, calculation, and induction. To give the matter an appearance as though that which depends exclusively on experience could also be constructed *a priori* is a barren shadow-boxing, a relapse into antiquated metaphysics. This objection would be completely justified if it did not have its ground in a misunderstanding. Here there is no question at all of deriving real facts from our own imperfect, impotent concepts; on the contrary! our task is to lead the facts of experience back to the power-concepts, without which they, in their antilogical reality, would stand before consciousness as blind facts. If it is in conflict with the scientific method that one, with the help of experience, strives to derive the laws of things from their concepts, how then will one defend the procedure of mechanical physics? It is, after all, evident that the laws for the impact of hard and elastic bodies

cannot possibly be found by way of experience alone, since no body is either perfectly hard or perfectly elastic; they must necessarily be derived from the real-concepts: hardness and elasticity.

From the ideal side the real-concepts are reflected in the all-comprehending self-unity; from the real side they are inherent in the things. It is the latter that in the present connection especially concerns us. The actual contains possibility to another actual; the actual gases oxygen and hydrogen contain possibility to water. In order that the possibility may be actualized, conditions are required; the conditions have the actual's immediacy and yet correspond in reflection to the possible. Chemistry has examples in abundance. When the salt is decomposed, that is, goes back into its concept, its possibility, the acid and the base step forth in antilogical reality, and conversely; nothing but outbursts of power in another. The real-concepts have a peculiar affinity for the antilogical; this affinity is originally determined by the relation between power in another and self-power. The chemist may concede that the oxygen and the hydrogen in a certain way perish in the water, namely insofar as by the combination they give up their particular properties, so that a new body with new properties arises; but that this can be regarded as a return of the realities to their real-concepts he will hardly concede. He will, in consequence of the atomic theory, on the contrary reject the transformation and assert the difference of the composite atoms from the simple atoms. The water-atoms are decomposable, for each water-atom consists of one oxygen and two hydrogen atoms; but the atoms of oxygen and hydrogen are, as simple atoms, indecomposable. The ontological reversal from reality into concept, from concept into reality, becomes by this mode of consideration highly suspect. Yet wrongly. It is finitude's, otherness's, real discretion on which the emphasis falls, but this real discretion is so far from conflicting with the real-concept's logical essence that it on the contrary confirms it: only by the discretion's antilogical elements entering as reflexes into mighty comprehension does the concept acquire the character of real-concept. The composite atom cannot possibly be regarded as a mere arithmetical sum of two or more simple atoms; for the sake of aggregation alone a mutual attraction must here be presupposed. Even if the attraction were—what, on account of the peculiarity of the affinities, it cannot be—merely mechanical, then the

mechanical attraction, according to what we have seen in the foregoing, would alone be sufficient to assert the concept's validity. The oxygen and the hydrogen could not possibly combine chemically if they had no affinity for one another; but mutual affinity they could not possibly have if their real-concepts did not correspond to one another; but the real-concepts could not possibly correspond to one another if they were not originally comprehended in one and the same comprehension. In the oxygen, the hydrogen, and the water we have three real-concepts, two co-concepts and a concretion-concept determined thereby. When the co-concepts exist with antilogical reality, then the concretion-concept is a possibility; when the concretion-concept exists, then we have in this reality the co-concepts' possibility. The transition from possibility to actuality presupposes conditions, but takes place by an outburst of power.

It has been intimated above that the positivistic assurance of the immutability of the laws of nature stands, according to St. Mill's admission, on rather weak feet. But even if this weakness is overlooked, even if it is conceded that a merely empirical induction can give us a maximum of probability that a B will invariably follow upon an A, is any essential insight thereby gained? By no means. There is a difference between *certainty* and *insight*. Suppose the relation between the hypotenuse and the legs had been found practically by a measurement of the triangle's sides and squares constructed thereon, then repeated measurements of right-angled triangles could indeed give a certainty about equal to that which a geometrical proof gives; but only the proof gives insight, the measurement by itself gives no insight. All insight is conditioned by this, that the representation of the one encloses the requirement of the other, that the one cannot be posited without the other having to follow, that the reality of the one bears within it the concept of the other. If the hypothetical proposition "if A occurs, then B must follow" is held fast merely empirically, then there is here no insight, however great the certainty may be. One will ground the phenomenon by enumerating its conditions, but however many conditions and intermediate determinations one enumerates, one still does not reach the ground; for it stands with the conditions as with the conditioned: the individual conditions are themselves phenomena. Instead of a grounding of the phenomenon one reaches only a summation of phenomena, which each in turn must be grounded by a summation of phenomena; the grounding is a continued demand

for grounding, but the ground flees away into infinity: insight is never reached. One can, with a maximum of probability, get certainty about many things and about the connection of many things, without however attaining insight, rational insight into any thing.

A rational insight into the connection of things is only possible under the presupposition that there is reason in the things, that the things are realized concepts. The concept realized in the thing is the thing's nature. That every thing acts according to its nature means that every thing acts in consequence of its concept; but what is the acting cause? For this question the problem of concept and reality presents a new side. The concept seems not to be able to be cause: the concept of gravity does not weigh, the concept of fire does not burn, the concept of a stone kills no dog. It must then be the thing that is cause. But when the thing can act only in consequence of its concept, then the concept must surely be the cause of the thing's being a cause. What does this lead to? Quite directly to a distinction between two kinds of causes, ideal and real, and thereby to a more penetrating investigation of the relation between *ideal and real causality* on the whole. Such an investigation is of importance for the sake of insight and scientific cognition. To make matter and force into causes, without troubling oneself further either about the concept of matter or about the concept of force, is an easy matter; to make the real cause logically one with the concept of the cause is not exactly difficult either; but in the first case one excludes all insight, in the last all reality.

The logical-antilogical outburst of power, which transforms the concept into reality, transforms at the same time the ideal causality into the real.

That the cause can act only by virtue of the unity of concept and reality is seen from this, that acting and activity can take place only in consequence of the same unity. The thing as thing in antilogical immediacy cannot act. And why not? Because immediacy, sharply and exactly held fast by itself, means that the concept's content, and therewith possibility to another, is exhausted in the thing's existence; the only thing the thing in this case is able to do is: to exist. With exhausted concepts the things would exist side by side, excluding one another, but for the rest have not the least to do with one another. Herbart's absolutely positive reals can serve as an example

of this. This acute thinker, persistent in exact analyses, suffered from the fixed idea that unconditionally independent reals should be able to be affected by one another without the positive in them betraying anything negative. A curious contradiction¹⁵! Under the mutual affecting the reals must precisely lose their absolutely positive character and sink down to becoming relativities. That it can no more be the concepts which, held fast by themselves in logical form, produce the things, is self-evident. The concept of water can as little produce water as one can drown in the concept of water. The thing's concept is its possibility, a possibility that lies hidden in other things' actuality. Only by the actual things having possibilities in themselves to other things are they able to act. Of several freely existing masses each single one has in its actuality the possibility of changing the others' place in space; it is this unity of actuality and possibility that is expressed in the activity we call mechanical attraction. Two pieces of wood cannot be rubbed against one another without the possibility of the one having to correspond to the actuality of the other; light-activity cannot

¹⁵The propensity to give empty verbal explanations instead of a real interpretation of facts, and the weaknesses of which metaphysicians, for the sake of the system alone, often make themselves guilty, F. A. Lange (*Geschichte des Materialismus und Kritik seiner Bedeutung in der Gegenwart*. Iserlohn. 1866. S. 463.) has aptly characterized: "Das absolut Einfache ist auch keiner inneren Veränderung fähig, weil wir uns diese nur in der Form wechselnder Ordnung der Theile denken können. Deshalb sagt Herbart auch nicht, dass die Realen auf einander wirken, sondern dass sie Einwirkungen von einander erleiden *würden*, wenn sie diesen nicht durch einen Akt der *Selbsterhaltung* Widerstand leisteten. Als ob damit etwas andres gesagt werden könnte, als mit der Annahme einer einfachen Wechselwirkung! Waitz legt in seiner Psychologie (S. 81) viel Werth auf den Unterschied zwischen *Dispositionen* zu einem Zustand und wirklichen Zuständen. So geht es in der Metaphysik. Zustände darf die Seele nicht haben; bei Leibe nicht, sonst ginge ja ihre absolute Einheit verloren! Aber Dispositionen, das ist ganz etwas andres; „Strebungen“, warum nicht? Der Metaphysiker widerlegt mit einem enormen Aufwand von Scharfsinn alle möglichen andern Ansichten, und wo er seine eigne Meinung entwickelt, schiesst er einen logischen Purzelbaum von der gewöhnlichsten Sorte. Jeder Andre sieht, dass eine Disposition zu einem Zustand auch ein Zustand ist, dass Selbsterhaltung gegen eine *drohende* Einwirkung nicht ohne eine, wenn auch noch so feine *wirkliche* Einwirkung denkbar ist. Der Metaphysiker sieht dies nicht. Er hat sich mit seiner Dialektik an den Rand des Abgrundes getrieben, alle Begriffe hundertmal herumgewendet, hervorgezogen, weggeworfen, und endlich *muss durchaus und durchaus etwas gewusst werden*. Also die Augen zugeedrückt und den *salto mortale* herzhafte gemacht — von den Höhen der schärfsten Kritik hinab in die allgewöhnlichste Verwechslung von Wort und Begriff! Ist dies gelungen, dann geht es munter weiter. Je mehr Widersprechendes in die erste Grundlegung aufgenommen wird, desto freier lässt sich schliessen, wie man denn bekanntlich aus mathematischen Sätzen, welche den Faktor Null in versteckter Weise enthalten, oft die merkwürdigsten Dingen ableiten kann." It is of course self-evident that a metaphysician's error can as little be charged to metaphysics as a mathematician's miscalculation to mathematics. If the mathematician subtly defends his errors, when they are clearly pointed out, instead of openly admitting them, he does not thereby compromise mathematics, he compromises only himself. The same holds of the metaphysician and metaphysics.

be given unless the light-giver's actuality corresponds to the ether's possibility, and conversely. Since now actuality is reality, and possibility concept, it is seen from this that ideal and real activity, ideal and real cause, must presuppose one another mutually.

The unity of ideal and real causality is a unity in opposition, an opposition-unity. From the side of reason the natural order of things makes the impression of an infinite, in all parts coherent whole; not even the smallest part can withdraw itself from the power of necessity, for everything subsists in infinite reciprocal action; it is a world of inner, essential relations, a world of concepts of ideal causality. From the standpoint of the sensible experiences, on the other hand, the world of realities shows itself as a world of chance, of outward conditions and real causality. According to the connection of concepts there has, for example, from a combination between silicon (silicium) and oxygen arisen silicic acid, from a combination between potassium and oxygen potash, from a combination between aluminium and oxygen alumina, and from the mutual combination of these combinations silicate of potash-alumina (feldspar)—all essentially in consequence of ideal causality. The one-sided concepts are contained in the more all-sided ones, and every trace of chance seems to have disappeared. By analysis of the concretion-concept feldspar we come to the co-concepts silicic acid, potash, and alumina; by analysis of these still concrete co-concepts to the elementary concepts of oxygen, silicon, potassium, aluminium—with reflected necessity on account of essential relations. If we begin with the elementary concepts and apply synthesis, we get the same necessity within the logical. But in the antilogical sphere of the realities something quite different shows itself. Here we meet circumstances, chances, and contingencies on account of outward relations. The oxygen and the silicon can here exist each by itself, without silicic acid arising; silicic acid and potash are found each by itself, without silicate of potash forming, and so forth. In the circle of the outer conditions every outburst of power is dependent on intervening chance. The outburst, antilogical in the contingency, is in the necessity logical: the reciprocal determination of contingent and necessary characterizes the law.

This leads us a step further. There is in the system of real-concepts a difference between concept-values, marked by this, that some concepts apparently lie nearest to

necessity, others nearest to contingency. Concepts such as earth, water, salt, acid, base, and the like appear as essence-concepts, substance-concepts, concepts of necessity; while others, such as: gravel, heap, aggregate, conglomerate, and so on, are formed in an entirely contingent manner by the coincidence of concept-consequences that do not essentially concern one another; such concepts are owing to contingency to such a degree that they do not even seem to deserve the name of concepts. This distinction between concepts of substantiality and of accidentality has a claim to attention, for the solution of the problem of reality is dependent on how it is interpreted.

If we begin from the contingent and concede that contingency makes the concept nominal, then the concept gravel is only a denomination for a heaping-together of parts, but no objective real-concept. The Positivist will smile when he hears that the concept gravel too is to be included in the eternal comprehension and have its ontological origin from an all-comprehending self-power. But when the concept gravel is nominal, what then is the concept granite? Also nominal! When the concept granite is nominal, what then is the concept feldspar? Naturally also nominal; the formation of feldspar has, after all, been conditioned by outward relations. That this mode of consideration is false shines forth from its consequence; for the consequence is that all objective real-concepts must disappear and give place to nominal designations of concept-less facts. The absurdity and superficiality herein has been sufficiently pointed out above; we are then compelled to begin from necessity. Just as in all real necessity there is an antilogical moment of contingency, since the really necessary is always *conditioned*, so there is in all the contingent a logical moment of necessity; if it were not so, there would open up in existence a wide field where the contingencies could carry on their play without regard to the laws.

There have been carried on, in the history of the sciences, particularly of philosophy, extensive disputes about whether, besides the physical causes, one could also assume final causes and ascribe to these objective validity. By distinguishing between the outer and the inner purposiveness, Kant has held that, for the organic formations, one ought to make—not indeed a constitutive, but nevertheless a regulative—use of the principle of purposiveness; but even the regulative use seems more and more to sink in credit. The obscurity has its ground in the fact that the relation between ideal

and real causality has not been sufficiently investigated.

When one without further ado separates the things from their concepts and, with denial of the ideal causality, imagines that one has enough in the physically acting causes, the final causes cannot possibly acquire any objective significance. But that this tearing-loose of the real from the ideal is unscientific will gradually become evident through a more thorough treatment of the problems of knowledge and of reality. Both the law of objectivization and the reciprocal determination of the logical and the antilogical in the outburst of power prove that the real causality has its ground in the ideal. When one one-sidedly clings to particulars, contents oneself with dissection, and blindly makes the whole into a result of the parts, then it is quite true that all talk of purpose and end must become nominal and superficial. Every finite attempt to fix something as end and something else as means founders on the infinite reciprocal action of conditions and conditioned terms; the alleged higher sinks down to the level of the supposedly lower, and conditioned necessity becomes sole ruler in the realm of things and laws. If reason is to come into its right, if a scientific insight is to be possible, then every approach to the solution of the great problems must at all points point toward a development of the parts out of the whole, toward the grounding of the real totality in the ideal, toward a world-design with an all-comprehending subjectivity as its author.

In the real-concept *design* lies the unity of ideal and real causality, in the concept of design purpose, and in the concept of purpose again the concept of means. The purpose, originally seen, is that requirement of subjectivity that the plan in the whole, the definite design, shall be actualized through a reciprocal development of the parts among themselves. The design itself is a system of designs: no part and no whole can give itself design, but every part, every whole acts and must act by virtue of its peculiar design. There must, in the name of reason, be a whole in order that there can be parts, there must be a higher in order that there can be a lower, there must be purpose in order that there can be means. The unscientific arises only when the finite subjectivity presumes to survey the plan, determine the aims, and apportion sun and wind between objective purposes and means.

The fundamental question is how the subjective in reality relates to the objective.

This problem itself comes into existence with the organic formations. What is a living organism, indeed what is life? Life is a conditioned self-activity, and the product of this activity is the organism; that is the shortest answer we can give here. The self-activity conditioned by matter exhibits a self-working-out, though restless, equilibrium of ideal and real causality. At the lower, elementary stage of development, the ideal causality, the ontologically subjective, is—what we have often enough emphasized—present everywhere, but so hidden in realities that the things act as matter-subjects by their properties upon one another: masses, molecules, atoms are real causes, physical otherness-causes on account of the hidden self-cause. With life's organizing activity the relation is reversed: the otherness-causes sink down to conditions and means for the self-cause coming to light, the self-actualizing ideal subjectivity, which in reciprocal action with the manifold of matter-subjects makes itself the ruling center and shows what the purpose is. In an enigmatic manner the double-sided causality separates into two relatively independent causalities, two heterogeneous principles, the ideal and the real; this must then lead the inquiry further.

III. The Problem of the Heterogeneous Principles

Among the most conspicuous problems of the human understanding belongs, without doubt, the one that revolves around the relation between life and organism, between soul and body. This problem obtrudes itself as if of its own accord, and it is then no wonder that both in earlier and in more recent times it has given occasion to a multitude of different hypotheses, and that these hypotheses, each in its turn, have competed for the dignity of being exalted into dogma. Nor has any problem lain nearer to hand when it was a question of a striking example of the barrenness of philosophical speculations and the imperfection of all human knowledge. If one grapples with this problem, one will soon make the discovery that it has something Protean about it and easily slips away from him who does not rightly know where he is to grasp it in order to hold it fast. One may start from the presupposition, which appeals to sound sense, that life is different from the organism, that the soul is a relatively independent being in opposition to the body, and yet, by the further course of the investigations, be led to

the recognition that soul and body, and then of course also life and organism, cannot each have their own subsistence, but must be assumed to develop out of one and the same fundamental principle; the problem is then this: *is the fundamental principle originally to be set in the ideal or in the real?*

If one makes the ideal principle absolutely valid, conceives life as Idea and the soul as the life-Idea's self-reflection in its immediate other, then the organism becomes a phenomenon of life, the body a phenomenon of the soul. If one, conversely, makes the real principle absolutely valid, then life becomes a resultant of the forces acting in the organism, and "the soul-specter," a phantom formed from brain-functions, shows itself only as a revenant from the darkness of Scholasticism. What especially makes the matter complicated is the circumstance that, however irreconcilable the opposition is between Idealism and Materialism, it is nevertheless unavoidable that the Idealist must express himself materialistically about the psychical, and the Materialist idealistically about the bodily, when it comes to the point. "The brain thinks, just as the stomach digests"—this proposition is materialistic, insofar as it places the activity of digestion on the same level as the activity of thought. The activity of thought is ideal; the Idealist knows no purer expression for ideal activity. In wishing to make the ideal activity material, the Materialist comes precisely to make the material activity ideal. The Idealist, who on account of the unity of being and thought lets matter think, must of course also let the stomach think, conceive the activity of digestion as a dialectical conceptual process, and thereby comes, in his efforts to make a material activity ideal, to make the ideal activity material. Insofar as the Idealist will in any way enter upon particular determinations of organs and organic conditions, he must necessarily speak as though matter really were material, and of such categories as bones, muscles, nerves use words and expressions that immediately correspond to our representations of the bodily. The same holds in the reverse sense for the Materialist when he speaks of the psychical. However materialistically the psychical functions are conceived, he is nevertheless compelled to use words such as sensation, feeling, representation, consciousness, and so on; but already the immediate and natural understanding of these words transports us with one jerk from the material sphere over into the ideal. When the Materialist treats of the consciousness of the brain, the spinal cord, the

ganglia, he cannot avoid distributing the lower and higher consciousnesses among organs, so that it looks as though consciousness were after all something ideal by itself; he lets, after all, the different consciousnesses melt together into a kind of consciousness-unity, without being able to fuse the organs into a similar unity.

One might on this account be tempted to the assumption that the opposition between Idealism and Materialism was not essential, that the dispute was only a dispute about words; but this is by no means the case: the opposition is one of principle. From the idealist side the matter is understood in such a way that the material activity is semblance and appearance of the ideal; materialistically it is understood in such a way that the ideal activity everywhere becomes semblance and appearance of the material. That there is here semblance and appearance on both sides proves that reflection is in movement, that there is a struggle for a monistic decision. The merely monistic unity is, however, an ambiguous unity, and so long as one struggles for an ambiguous unity, the struggle can be continued in all ambiguity. The old Dualism was mechanically miraculous, but it was not ambiguous. The miraculous science has thoroughly overcome; but the modern Monism, which has set itself in Dualism's place, suffers from an ambiguity that will hinder every true scientific advance, so long as it is allowed to remain standing.

In order to remove the ambiguity it is first of all necessary to come to clarity about how far there is at bottom any difference of principle between the lifeless and the living, and, if such a difference indisputably takes place, then to investigate wherein it actually consists, and what the distinguishing marks are by which it is to be known. Without dwelling on comparisons and descriptions, which from a natural-historical standpoint may be orienting for practical use, we will attempt to hit the matter's core point and direct attention to what, according to our conception, must be the decisive thing. As the distinguishing characteristic of lifeless activity of whatever kind—mechanical, magnetic, electrical, chemical—we hold fast what physics has demonstrated as a law, that action and reaction under all reciprocal actions of material terms must exactly correspond to one another, so that no self-governing midpoint can be assumed. As the mark of life-activity, on the other hand, it is emphasized that, under the material points' mutual action and reaction, an ideal midpoint forms

itself and therewith a conditioned self-activity, which alters and governs the parts' reciprocal action. The facts corresponding to this are metabolism and form-giving, not immediately each by itself, but in active union. A crystal-form can maintain itself when metabolism is excluded; a metabolism can take place and the form be disturbed; herein is no trace of life-activity. But when a metabolism takes place in such a way that a typically determined form-development is thereby maintained, then we regard this as an unmistakable sign of life's organizing activity. The activity's ideal midpoint cannot be mathematically localized like a sphere's center of gravity, which is only a resultant of the parts' gravity; nor can it be either a proper material point or a metaphysical real, for in that case it would have to act according to its properties like other material points or reals. Every whole that rests solely on reciprocal action of real parts according to properties must—what the theory of potential-functions proves exactly—be punctually subject to the law of action and reaction: here is no trace either of self-active unity or of governing midpoint. Everywhere, on the contrary, where cells form themselves and life manifests itself, there is an indication of a peculiar need, peculiar requirements, which demand their own housekeeping; life-activity has the stamp of a governing something, which through its other, its material, will assert itself and work for its preservation and self-development. Characteristic of lifeless things is their complete indifference to the state in which they find themselves. No one will assume that in water there is a hidden longing to become ice, or in ice a quiet urge to pass over into vapor; on the contrary, a plant sprouting in the dark, which stretches toward the sunlight, may well be said to betray a striving and longing. It is a distinguishing mark of life that it has a goal: self-development and self-preservation is the goal. To struggle for one's life is to have a purpose. It must in high degree surprise everyone who has not yet given up all hope of rational insight, that researchers of positivistic zeal for an exact cognition of conditions and causes have rejected every representation of final causes, and yet, as regards the development of the organic forms, chosen the watchword: *Struggle for Life*.

With these distinguishing marks for the lifeless and the living we stand before *the problem of the heterogeneous principles*.

The reality-principle is recognizable enough. At the present stage of science

there can be no doubt that the organic formations take place in full agreement with the general laws of nature just as well as the inorganic; for mechanical attractions, chemical affinities, polar tensions, the relation between work and living force, and so on, the same fundamental laws hold in the organism as in elementary nature. The ideality-principle can, according to our foregoing, also not be dismissed. The marks of self-activity, self-development, self-preservation are far too conspicuous to be able to withdraw themselves from the unprejudiced gaze. When these indications of selfhood are nevertheless overlooked or effaced, then it is evidently not the fault of the facts; it is only the Positivist who, from lack of insight into the ideal, supposes that he finds his advantage in denying what he cannot explain. The ideal principle by no means calls upon us anew to introduce either a peculiar vital force on the same level as the elementary forces or a soul-substance, a proper real, that should sit here or there like “a parasite” in the body; but it demands of us that we do not deliberately close our eyes to what in the living and then especially in the ensouled organisms is unmistakable, a self-activity different from matter-activity but conditioned by matter, a peculiar articulating, self-developing, self-preserving activity.

Perhaps one will object that the opposition of two heterogeneous principles here set up is only a rehash of an antiquated Dualism, which the monistic science of the present day neither can nor will recognize; we then ask whether present-day Monism can exempt science from bowing to facts. If it is possible for science to show how physical currents and molecular changes can transform themselves into sensations, feelings, representations—well then, Monism is right, and Dualism falls away of itself. But so long as the human understanding is able to make a distinction between material conditions and ideal causality, so long as the supposition that the same thing which from the one side shows itself as outward and material can from the other side show itself as an inward, self-apprehending ideal is and remains meaningless—still more meaningless than the assumption that tone and sound-figure are the same, only apprehended with different senses—so long stands the opposition of two heterogeneous principles, the matter-activity’s and the self-activity’s, in force as an incontestable fact. The highest that one will ever be able to reach by way of the immediate observations is a thoroughgoing parallelism of matter-activity and self-activity, of bodily and psychical

functions. But a plain and simple paralleling gives us no real insight; the Dualism must have its ground in an essential unity, and the question then becomes how far such a ground of unity can with any probability be pointed out.

It is an age-old view that the whole of nature is ensouled and living, that life is not limited to the organisms alone, but even embraces what one otherwise calls dead matter. This way of seeing is false insofar as it is held fast in the form of imagination and representation; but, brought under the general law of comprehension, it may well be said to contain a moment of truth. What is misleading in Hylozoism is: first, a one-sided propensity to regard all stirring, all movements, especially all continued circular movements, as unmistakable signs of life—there is then life in the solar system, life in elementary changes, in geological formation-processes, and so on; secondly, an ambiguous use of the word sensation: the cliff senses the stroke of the lightning, the iron senses the magnet's nearness, nerves and ganglia sense physical impressions, as we sense a well-being or an ill-being; thirdly, a mystical application of the word drive, especially formative drive. By the use of vague, indeterminable analogies, symbols, and ingenuities one gradually breaks down every barrier between the living and the lifeless and gets the qualitative difference reduced to a vanishing difference of degree: the more outwardly, mechanically, and chemically the signs of life are conceived, the more fluid it goes with hylozoistic fantasies.

Under the standpoint of the concept, on the other hand, the representation of a universal life spread throughout the whole of existence can be understood by the ontological comprehension in which all that is is reflected. The self-comprehension that objectivizes itself in the system of real-concepts lies at the ground of all transitions from possibility to actuality in the world of realities. Through all series of physical causes, conditions, and effects there goes a stream of ideal cause-moments and ideal effects; this never-stopped stream, encircling ideality's selfhood, can in logical abstraction be conceived as a shading of a universal living, a universal self-activity, corresponding to a universal life-concept. But further one does not reach by this way.

If life is really to come into existence, then its existence must just as surely have its particular real-concept in the whole design of existence as either the oxygen or the water or the hydrocarbon or the ammonia or whatever else one will name; only with

the express difference that life's concept is a selfhood-concept with a surplus of ideality, the concepts of water, hydrocarbon, ammonia, on the other hand, otherness-concepts, matter-concepts. The problem then concentrates itself in the task: *to make clear the fundamental relation between selfhood-concept and matter-concept.*

In the matter-concept the self-activity is latent, just as the ideal causality is latent in the physically acting cause. The physicist knows that in a body there can be heat which does not act on the thermometer, because the activity is converted into a state-form, and only comes to light again when the state-form is changed. In like manner it holds that the ideal causality is never immediately noticed in physical causes or in that outburst of power by which the transition from possibility to actuality takes place under the form of otherness. But the latent causality is nevertheless just as little to be regarded as nothing as the latent heat. On peculiar conditions, under peculiar circumstances, the selfhood-concept—which surely, as fully as the otherness-concepts, must be a concept of ideal power—can set its possibility over into actuality and come into existence. Let us test how this will appear in fact. So long as the so-called organic substances—oxygen, hydrogen, carbon, and nitrogen—act merely according to the laws of otherness, the reciprocal action produces no surplus of ideality, nothing in which a selfhood-cause can show itself; it remains at elementary formations. If, on the other hand, the reciprocal action between atoms or molecules takes place under such conditions that a surplus of ideal causality arises, which cannot in the manner of otherness be equalized in action and reaction of material parts, then there forms itself, out of the ideal surplus, a midpoint of self-activity: life begins its wondrous work.

Although the opposition between the ideal and real principle is thereby asserted, it will nevertheless easily be seen that this Dualism does not make a breach in the unity of existence, but on the contrary serves to ground the true, well-understood Monism. The dispute about *generatio æquivoca* is not yet at an end, nor has one given up the hope of being able to produce a living cell. It will be understood that the possibility of such a production by no means stands in conflict with the assumption of heterogeneous principles; for life-activity must just as surely have its law-fixed conditions as any other activity. On the contrary, it must be expressly emphasized that cell-productions by artificial means cannot be set up as proofs that life is only a

resultant of physical forces. Selfhood's ideal midpoint can in the beginning be so weak, so hidden and lost in the matter-activity, that it looks as though the life-principle were only an imagination; but as the formations advance, it shows itself ever more clearly that the material changes are subordinated to the self-activity, just as it also shows itself how dependent the self-active is on matter and matter-activity.

The organic functions thereby take on the stamp of doubling. No material part, no matter-subject is able to carry out any selfhood-function whatever. Propositions such as: "The ganglion feels, the brain thinks" are not scientific; one might just as well say: "Chlorine has an inclination for the metals," "The magnetic needle is attentive to the North Pole." Conversely, the self-active in the organism cannot accomplish the least without a corresponding matter-activity.

The *organic* functions are from first to last *double-functions*, each function a doubling-unity of matter-activity and self-activity. Herein lies that the matter-activity can now be so predominant that it hides the self-activity, and the latter again, as in pure thinking and willing, take on the appearance of pushing the matter-activity back. Oscillations of the matter-functions' and the selfhood-functions' alternating preponderance can call forth manifold expressions of interferences, polarizations, of received, given-off, and stored-up work in different measure; but whether by physiological observations, psychophysical measurements, and psychological interpretations it will ever be able to be brought to the point that exact analyses of the oscillations obtain a more reliable ground than the Herbartian mechanism of representations, we must leave undecided. The first thing needful is that the proposition about the double-sidedness of the functions be subjected to a critical examination.

Regarded from the side of the matter-functions, the organic life-unity is a kind of collective unity: so many cells, so many lives; so many organs of consciousness, so many consciousnesses. The collective unity is then more closely interpreted as a disciplining unity of connection: the smaller lives are subordinated to the greater, the dimmer consciousnesses melt together in the clearer; but the collective is and remains the characteristic. From the side of the selfhood-functions, on the other hand, the unity shows itself as an all-concentrating self-unity: one life, one soul, one consciousness, one self in the human body has in older psychologies been made the

norm for every judgment of lower-standing organisms. But the representation of the soul as an in-itself indivisible, unchangeable, and therefore imperishable single being has the unprejudicedly advancing physiology given the death-blow, in that it has by incontestable facts proved that life not only in vegetative but even in animal organisms can be parceled out, and the psychical divided. Only by conceiving the organic functions as double-functions do we bring it to the point that both the one-sided ways of seeing come to their relative right. Since the selfhood-functions are everywhere conditioned by the matter-functions, the self-unity must necessarily be reflected in the unity of connection, and have its validity along with the division; but since the matter-functions again, as regards life and the psychical, are only means and conditions for the selfhood-functions, and the psychical selfhood-functions reflected moments in the ruling self-unity, then the old representation of the soul as a relatively independent being nevertheless gets its significance.

But what now is this psychical being? It cannot possibly be any immediate substance, for an immediate substance is only a substratum. To speak of a soul-substance, a soul-real, is, when we make the matter clear to ourselves, the same as to speak of a substratum-activity, analogous with a matter-activity, while one nevertheless imagines that one is speaking of a self-activity essentially different from matter-activity. On the contrary, it is in full agreement both with the concept of self-unity and with the physiological facts to speak of a unity of ideal causality that constantly strengthens itself under material conditions, a self-unity which can in manifold ways be hindered and weakened, but also, under favorable conditions, show a disposition to a concentration whereby it raises itself to ever greater reflected independence and ideal substantiality.

If the independence resulting from self-activity is to be more closely investigated, then the problem takes on the character of *a problem of freedom: the real and the ideal principle set themselves against one another as necessity against freedom*.

The conflict between freedom and necessity does not first arise with arbitrariness and the self-conscious will's choice in the finite; its origin coincides with the origin of life; every monstrosity, every embryonic abnormality can be an example: the principle of selfhood is the principle of freedom, just as the principle of otherness is that of necessity. Absolute necessity is a concept that cannot exist; real necessity belongs

to otherness and thereby to relativity. If one supposes that one has the absolutely necessary in an infinite totality of conditioned terms, then this is only an imagination. Should such a necessity be absolute, then it would have to master its terms and conditions and, in a mighty comprehension of the all, assert its unity; but precisely thereby the mighty unity would, after all, be a self-reflecting unity, a self-power-unity, a freedom-unity.

One has sought to hold fast the absolute unity of freedom and necessity from the side of necessity in the category: free necessity (*libera necessitas*), from the side of freedom in the category: necessary freedom (*libertas necessaria*); that is metaphysical formalism. Necessity does not become unconditioned in infinite series of connected conditions, it becomes on the contrary conditioned to infinity; nor does freedom become unconditioned by pushing the conditions away from itself, but by self-actively appropriating them and making them its own conditions.

The absolute freedom-unity can be knowing, mighty, self-determining, all-determining without being arbitrary. When in the analysis of the ontological concept of subjectivity we nevertheless introduce categories such as arbitrariness, choice, decision, these by no means denote separate actions, but determinations of finitude, antirational moments, which dissolve in the infinite reflection and yield reflexes in the concept of absolute self-determination.

The question of the content of self-determination leads us immediately over into the circle of otherness, of the relativities, of the finite conditions and causes, and here we meet necessity. That which happens with freedom must just as surely have a ground in another as that which happens with necessity, for no definite willing is possible without something's being willed. The real ground of the necessary, which is not one with the sum of the conditions, but reflected in their relations, is subject to the unity of connection; self-determination, on the other hand, transforms the real grounds into *motives*. Necessity with the physical causes is reflected in nothing but real-grounds; freedom's ideal causality in nothing but motives. It is only an outward, superficial representation that the absolutely self-determining freedom-unity should be able to treat the connection of things, the world of laws, arbitrarily, or proceed by leaps and leap over the real-grounds; it lies, on the contrary, in the fundamental

relation of necessity and freedom that the motives in the ideal must exactly correspond to the grounds in the real.

At the stage of finitude the conflict between freedom and necessity shows itself as a conflict between conditioned self-activity and the conditions to which it is subject. The ensouled organisms suffer under hindrances, need, and constraint; the self-conscious subjectivities apprehend the constraining necessity as fate. Then it is said that the power of fate makes man's freedom into nothing. Wherein, then, consists man's freedom? We answer: In self-conscious, conditioned self-activity. How far the self-determined activity reaches, and how much it accomplishes, depends on inner and outer conditions, but it is annihilated only when self-recollection ceases, and the light of consciousness is extinguished. Self-consciousness can raise its determining willing up before itself and, by a peculiar kind of abstraction, free it from every constraint; it then looks as though the free will stood independent over against the fateful necessity, measured it with its eyes, and challenged it to single combat. Whether the will in outward action wins or loses is not the decisive thing; the decisive thing is that there is willing. It is not this or that finite thing that is chosen or willed, but the will chooses itself, chooses unconditionally to will. From this height of abstraction defenders of the unconditioned freedom-principle have categorically declared that the rational, self-legislating will is able to remove all admixtures of sensuous incitements and go against drive and inclination as the ship that has its own motive power can go against wind and current. Experience shows, however, that it cannot be done. And why not? Because pure self-determination is only an abstract expression for imaginary freedom. Not even in the moments of self-exaltation has the self-willing will been independent of impressions from another. A mood, a feeling, a goal of thought, an ideal of imagination has been co-operative. If we investigate such an ideal a little more closely, we shall discover manifold influences, reminiscences, experiences, examples, which in all concealment stand behind it, so that the will is never free of motives. But the motives are, after all, owing to impressions from another, regard for another; when attention fixes itself on these impressions and the regards thereby determined, the will becomes concrete, sinks down into the circle of conditions, and feels the weight of the motives.

The universal and yet concrete motive now becomes self-preservation, which again can be partly of a lower, partly of a higher kind. The claims of individuality are to be satisfied; the satisfaction is conditioned by an order of things in which necessity rules; there is then needed no great analytic art to discover how tightly the chains of conditions wind themselves about the individual's willing. The state of the outer world, the temperature of the surroundings, and the juices in the blood unite with the nervous system's physiological-psychological dispositions and make the will an organic product of real motives. Seen from this standpoint, freedom founders in necessity. Without waiting upon the worn-out theories—indifferentism, determinism, predeterminism, and their various shadings—we consider it sufficient to point to the problem itself: *The problem lies in the reciprocal determination of motive and will.* No will without motive; the strongest motive will always dominate the will: herein lies *the moment of necessity*. But the relation between stronger and weaker motives cannot be weighed mechanically; there is in the will's subjective energy a surplus of ideality that is incommensurable with the objective in the motive. It is in the highest instance the will itself that must decide which of the strong motives is to become the strongest: *the will is moved only in that it lets itself be moved*; herein shows itself the imperishable *moment of freedom*. The freedom-functions have the unmistakable likeness to the organic ones, that they are double-functions, functions of objectivity's real grounds and of the will's, that is, of self-determination's subjective energy.

The freedom-life in individuals is to be regarded from two principal sides, insofar as it partly manifests itself in single scenes and actions, and insofar as it displays itself in a ruling striving toward a definite final goal. From both sides the freedom-principle points toward a grounding that lies outside the boundary of science. The objective necessity that expresses itself in the connection of things furnishes a firm and secure ground for scientific investigations: the grounds are convincing, and the proofs compelling. But self-determination's subjective energy withdraws itself from science's control to such a degree that here appeal must constantly be made to the individuals' inner experience; but the inner experience is different in different individuals. The grounds are not compelling, but persuasive; for freedom-grounds must be appropriated with freedom. What use is it to speak to people who have their

life in nothing but finite interests, of a freedom that obliges to self-denial and the sacrifice of the temporal in order to win the eternal? They will not understand it. Even if they cannot point out contradictions in the conceptual development, the ideal freedom-enthusiasm will nevertheless in their eyes appear as an abstraction's flight from reality, a utopian longing toward a supersensible, an exaggeration, a fanaticism. They cannot understand it; for freedom-grounds are ethical-subjective, and ethical-subjective grounds find entrance only with subjectivities that are practiced in ethical self-exertion and will train themselves in the school of freedom. The freedom-principle is not a theoretical but a practical principle, a principle of faith; thereby it becomes not only heterogeneous with necessity, but, as we shall see in what follows, heterogeneous with science.

Scientific investigations of the essence of faith lead so deep into the mysteries of subjectivity that the problem of the heterogeneous principles in the last instance transforms itself into a decisive boundary-problem, *the problem of Religion and Science, Faith and Knowledge*.

It is in this respect remarkable to see how Comte, the founder of Positivism, after having begun with an objectivity of facts that excludes the subjective, ends by calling feeling and subjectivity to his aid and, in the name of religion and morality, lamenting the modern revolt of the spirit against the heart (*l'insurrection moderne de l'esprit contre le cœur*). His learned and clearly thinking disciple, Littré, has—not indeed without a certain melancholy, which does honor to his devotion to the master—pointed out this deplorable inconsistency¹⁶. Feeling, says Comte, ought always to rule over the intelligence; hence, objects Littré, just as in the Middle Ages philosophy was the handmaid of theology, so should the spirit now be the slave of the heart. Herein is something ambiguous. If Comte with his expression means nothing more than that the spirit, the intelligence in unity with feeling, is to work for the good and the beneficial, then there is no one who will contradict him herein; but if he thereby means that the whole governance is to proceed from the heart, then he blinds the heart and gives morality up as a prey to all sorts of excesses. If he means that the intelligence ought not to work for itself or strive after pure truth and abstract theory, then he mutilates

¹⁶ *Auguste Comte et la philosophie positive*. Paris 1877. S. 539 flgd.

humanity and robs it of its mightiest instrument for ennoblement and progress in perfection. It was not the heart, but faith, the blind faith in the authority of revelation, that held the spirit in medieval subjugation. Should the spirit's rising against this subjugation be pernicious for the human souls, then the Middle Ages must, historically seen, have more virtues and fewer vices than the more recent time; but history shows that precisely the reverse is the case. Comte sets the scientifically grounded faith (*la foi démontrée*) against the revealed faith (*la foi révélée*) and then demands that the intelligence shall submit itself to religion; but what does this mean other than that the spirit shall submit itself to its own work, thought to its own proofs¹⁷.

That the freedom-principle cannot find recognition in Positivism is a matter of course. By assuming the fact to be something objective in itself and holding to realities without real-concepts, the positivistic philosophy has from the beginning excluded every attempt at a more deeply penetrating cognition of freedom's subjective essence. The only scientific way from the objective to the subjective, from necessity to freedom, goes through the real-concepts. *Things are determined by their concepts, the concepts are determined in being comprehended, and they are originally comprehended by the all-comprehending self-unity, the ontological subjectivity.* If this assumption can be shaken, if it can really be demonstrated that there can be things without concepts, facts without laws, objects without objectivizing selfhood—well then, there can be talk of holding the necessary fast without freedom and of discovering the really true, the in-itself independent objective, by eliminating the subjective. But if every attempt in this direction, according to what has been made clear about the problem of knowledge and of reality, is found to be unreasonable and meaningless, then it stands unshakably fast that the whole objective existence is borne by objectivizing subjectivity, that the

¹⁷ Anfr. *Skr. III*me partie. Chapitre IV. Examen de l'opinion que l'esprit doit être subordonné au cœur. S. 545. En prétendant unir les principes du régime positif avec les conséquences du régime théologique, on tombe dans des contradictions implicites. Subordonner l'esprit à la foi révélée est une notion parfaitement claire; car la révélation émane de la divinité, et, quelque inconcevables que soient les mystères qu'elle ordonne de croire, il n'importe, une autorité devant laquelle l'homme n'est rien a parlé, et il doit se soumettre. Mais, dans le régime positif, que peut signifier la subordination de l'esprit à la foi démontrée, puisque cette foi démontrée n'est pas autre qu'une œuvre de l'esprit lui-même et le résultat d'une longue enquête qui a mis en lumière les lois immanentes du monde? C'est dire le même par le même que de dire que l'esprit se subordonne à une foi qu'il a faite, et énoncer une impossibilité que d'énoncer qu'il s'insurge contre cette foi?

necessary order of things has its ground in self-determining freedom. The things, the facts, which for our empirical investigations are the first determining thing, are then not in themselves the first; they are a derived, they exist only as outbursts of power. The real-concepts, which for our rational analyses are logically determining, are not the first logical thing: the system of concepts points toward an eternal logic in an eternal self-thinking unity. From all sides, through all determinations—be they real or ideal, logical or antilogical—the investigations point, as in converging lines, toward the all-uniting midpoint, the determining point of departure, the inner ideal causality for real causes and cause-series in outward infinity, that is, toward the original freedom.

But what and how much the divine freedom is able to do, no human being can know¹⁸. Science has, as regards the content, to hold to what really lies before it, what

¹⁸If anyone objects that the same holds of an all-comprehending self-power, we must call attention to the following. To penetrate into the inner movements of the eternal self-comprehension is certainly just as impossible for us as to fathom the secrets of freedom. One might for that matter just as well settle down with the Hegelian: the concept comprehends itself, as appeal to an ontological subjectivity, for both are in reality equally incomprehensible to us. But precisely in the determination of the *incomprehensible* it is important to be scrupulous with respect to *possibility* and *necessity*. Most aptly F. A. Lange remarks, concerning “einen nicht stichhaltigen Versuch in Ueberweg’s Logik (§§ 38–44)”: “Ueberweg bestreitet mit Recht die Art, in welcher Kant Raum und Zeit als *Form* der Wahrnehmung von dem *Stoff* derselben unterschied. Er geht sodann von dem Satze aus, dass die innere Wahrnehmung ihre Objekte so, wie sie an sich sind, mit materieller Wahrheit aufzufassen vermöge. Mit musterhafter Klarheit unterscheidet er das Wesen der Empfindung von dem Wesen der Dinge, durch welche dieselbe veranlasst wird. Nur das Wesen der psychischen Gebilde in unserm eignen Bewusstsein, glaubt Ueberweg, vermöchten wir genau so zu erkennen, wie es ist. Da nun unsre innere Erfahrung zeitlich verläuft, so hält er die Wirklichkeit der Zeit für erwiesen. Die Zeitordnung setzt aber die Gesetze der Mathematik voraus und diese setzen den Raum von den drei Dimensionen voraus, womit der Gang des Beweises abschliesst. — Abgesehen davon, dass der Fundamentalsatz wenigstens hinsichtlich der Reproduktion gerechten Bedenken unterliegt, scheint mir ein ganz bestimmter Fehler darin zu liegen, dass die Realität der Zeit in uns auf die Realität der Zeit ausser uns übertragen wird. *In uns* hat nicht nur die Zeit Realität, sondern auch der Raum, ohne dass dazu eine Vermittelung durch den Zusammenhang der mathematischen Gesetze nöthig wäre. Nun müssen wir allerdings aus dem Zusammenhang der Dinge in *uns* mit Nothwendigkeit auf einen correspondirenden Zusammenhang der Dinge *ausser uns* schliessen; allein dieser Zusammenhang braucht eben keineswegs Uebereinstimmung zu sein. Wie sich die Vibrationen der berechneten Erscheinungswelt zu den Farben der unmittelbar gesehenen verhalten, so könnte sich auch eine für uns ganz unfassbare Ordnung der Dinge zu der räumlich-zeitlichen Ordnung verhalten, die in unsern Wahrnehmungen herrscht.” *Geschicht. d. Materialism.* S. 497–98. — This can all be conceded; but from the incomprehensible there is a great leap to the impossible, and only when the impossible is reached does doubt cease. It is perhaps possible that a being can be so organized that it is only able to represent space to itself in two dimensions, and that our world of experience as a consequence must appear to it to be like a “Ding an sich” (anfr. Skr. S. 499); but in order not to make ourselves guilty of a *μετάβασις εἰς ἄλλο γένος*, we must guard ourselves against distracting side-considerations. The question here is not how many dimensions space may possibly

has been produced and is demonstrably produced in consequence of the laws; we must, in other words, know freedom by necessity.¹⁹ There can then lie in the depth of freedom possibilities of which science has no inkling or can have. The self-conscious life is in the highest sense interested in everything that concerns freedom; since now it is impossible for human knowledge to measure out the depths of freedom, there must on this account be life-questions, decisive freedom-questions, which science cannot answer. What does the eternal spirit intend with this nature, what is its actual meaning with the endless swarm of ensouled organisms, which, as it seems, are born only in order to suffer, and live only in order to die? Above all, what is its purpose

have, or what impressions different vibration-times may cause; but the question is: Can there be forms of space and time so essentially different from ours that for that reason they are incomprehensible to us? If this is assumed, then the unknown space-form must, not only on the whole, but also in each of its dimensions, be qualitatively different from ours. There must then be dimensions that are not dimensions, that is, dimensions which, although they are entirely incomprehensible to us, must yet be conceived as analogous with what we call dimensions. Likewise, as regards time, there must be successions so incomprehensible that they can only be conceived as analogous with what we call succession; hence: incomprehensible and yet not incomprehensible. If anyone finds this acceptable, then there must in his consciousness be a space for the incomprehensible that is more harmful than what is called the harmful space in the air-pump. A space that is not space, a time that is not time, is not merely something incomprehensible to us; it is something in itself impossible. That whose opposite is impossible is necessary; it becomes, for the sake of criticism, necessary to give up the barren skeptical game with incomprehensible analogies, necessary to recognize the a priori subjective forms as objectively universally valid. In the very same way it stands with reality, concept, and comprehending self-being. We do not assume that every reality must necessarily have its concept, and that this concept must lie hidden in other realities, because it is in fact less incomprehensible to us how a real-concept can by an outburst of power become reality than how ether-waves can be transformed into light and colors; but we assume it because we see that the opposite is impossible. We presuppose an all-comprehending self-unity, not because we grasp how an infinite, simultaneous comprehension of all concepts can take place, but because we see that concepts cannot possibly be thought without comprehension, and that comprehension is impossible without comprehending subjectivity. Otherwise with the particular concepts and their mutual relation; here there are countless possibilities, logical consequences, hidden transitions, which we do not grasp. It is in the name of science just as unreasonable to break off at an apparently unintelligible thing and declare the incomprehensible-to-us to be the in-itself-impossible, as it is a sign of fantastic overreach to operate with imagined possibilities and pretend as though one grasped what nevertheless is and remains incomprehensible to us. Strict science may by no means deny that the divine freedom has unsearchable possibilities; but it is entitled to make objections when a something that calls itself science wants the unsearchable possibilities scientifically searched out, when in pseudo-scientific form one is served with categories such as: *God's grace, God's disfavor, wrath, mercy, forgiveness, remission*, and so on. These are, after all, possibilities that only those can know who in consequence of their calling and dignity have free access to the Holy of Holies; let them then communicate to us the Godhead's secret counsels and decisions—yet, be it noted, in such a way that the communication takes place, not in science, but — outside science.

¹⁹Translator's note: the print here reads "med andre, Ord" — the comma is misplaced, and should read "med andre Ord," ("in other words,").

with man? Are the human souls destined to disappear with the dissolution of the present organs, or do they bear within them a disposition to a development infinitely continued on other conditions? Upon an answer to such questions science cannot enter, for possibility stands against possibility.

Already the psychological reciprocal determination of *real-grounds, motives, and will* reminds us how impenetrable the actual fundamental relation between freedom and necessity must be for finite consciousnesses. If one lays the emphasis on the motives' real grounds, then necessity steps forth in freedom's light, and what then will the spirit? A development of the possibilities contained in its own inexhaustible nature-ground! The visible world's design and this design's law-determined actualization is objectivization's expression for the infinite satisfaction with which the all-producing freedom enjoys its own grounded productions. Natural-necessity, which, objectively seen, is blind and conditioned, is in the free self seen through and willed; far from being something foreign and constraining to self-determination, it is on the contrary that system of real grounds which makes the will absolute by giving the motives objective validity. When it is then said that the spirit, with all alleged economy and apparent prodigality, cannot do otherwise than produce this real nature, this objective world with its phenomena and laws, then this will only mean that the absolute freedom, by determining everything according to its own nature, must absolutely satisfy itself. This is, so to speak, the realism of the freedom-principle.

But the freedom-principle is at bottom an idealistic principle. The freedom-idealism lies in self-determination's subjective inwardness: ideas, ideals, and ideal concepts also belong among the will's motives. It is then possible that the will, without withdrawing itself from the real-grounds and becoming arbitrary, can by virtue of ideal motives determine and articulate the possibilities in such a way that real-systems of a lower order are set as conditions and means for systems of a higher order. It is then possible that this nature, the universe in which we live, is only a grand introduction, a step on the infinite scale by which the eternal wisdom leads its work, its will-productions, up toward the goal of perfection; but the opposite is, after all, also possible. Where are we now? Is it now so that the whole development takes place within this visible universe, or are there real-systems of a higher order in which the completion is reached? We do

not know it; possibility stands against possibility.

In the same uncertainty we are entangled when the question of the all-determining self-being's care for the ensouled organisms, especially for the self-conscious souls, is to be answered. It is, after all, possible that the eternal spirit is infinitely indifferent to the weal and woe of the ensouled individuals; it is, after all, possible that the unchangeable law of nature, which sets a limit to enjoyment and bounds to suffering, must be the living beings' only consolation, that the ideality which can be distilled from self-conscious beings' anguish and pain does not benefit the individuals themselves, but is a sublimate of the impotent ones' resignation, an odor of sacrifice which the almighty freedom enjoys for itself alone. But it is, after all, also possible that the spirit's essence is love, that the apparent indifference belongs to that wisdom which solves all riddles, and will one day, in higher regions, explain itself into an eloquent testimony of the fatherly care with which the absolute self-being has from eternity willed to secure for the relative self-beings a thorough, gradual, and therefore painful attainment of the freedom to which they are destined. On which side now stands the real truth? We do not know it: possibility stands against possibility.

Are we herewith finished? By no means. On a neutralizing equilibrium of opposite possibilities it is impossible to live. No free rational human being can lead his life without a rationally determined view of life; but a definite view of life is only possible by virtue of a decisive choice between opposite possibilities: here is the boundary-line between Religion and Science, Faith and Knowledge. The highest that scientific insight can reach is to clarify the possibilities and show us the necessity of the choice; but for the choice itself science cannot be responsible: the responsibility rests on the choosing subjectivity. He who chooses to live on a view that sacrifices the individual for the universal, bends freedom down under necessity, and lets the self expire in infinite resignation, can just as little appeal to scientific grounds as he who chooses to struggle for freedom's personal ideals and rely on the omnipotence of love. Both choose in faith, and the choice of faith may just as little efface the scientific consciousness in the latter as in the former. If we must now concede that only those principles whose demands are justified by scientific grounds are scientific, does it not then follow with irrefutable consequence that the principle of faith cannot be a scientific principle?

It is not enough to present the faith-principle and the knowledge-principle as heterogeneous; for even when we hold to Newton's rule, *principia præter necessitatem non esse multiplicanda*, it cannot be denied that within science's own domain there are heterogeneous principles. Some of these—such as Materialism's, Spiritualism's, Positivism's, Idealism's—combat one another mutually, lay bare by reciprocal criticism one another's one-sidedness, and in this way prepare their own dissolution; but there are others that do not let themselves be neutralized in this way. The heterogeneous special sciences have not only each its material, its goal, and its method, but also, in consequence of the course of the investigations, each its peculiar principle: no encyclopedist has yet been able to derive all the sciences from one single principle; but since the sciences nevertheless, insofar as they are sciences, are homogeneous, the heterogeneity of the principles can only be relative. If we now limit ourselves to calling the faith-principle and the knowledge-principle heterogeneous principles, then we make ourselves guilty of an ambiguity. There must, after all, be a qualitatively decisive difference between principles which, with all their heterogeneity, fall within science, and a principle which, on account of its unconditionally subjective, personal peculiarity, falls outside all science; in order therefore to remove the ambiguity we must expressly impress that the principles of Faith and Knowledge are absolutely heterogeneous.

It might well seem as though the dualistic separation of Faith and Knowledge had significance only for those who choose to believe in a positive religion's supernatural facts, but not for those who hold to reason and build their religious conviction on an objective, scientific foundation. That is a great error; Comte's remark about "the modern revolt of the spirit against the heart" is, from science's standpoint, a forceful expression of subjectivity's undeniable claim to precedence in the religious. Let one say: "I cannot believe in an almighty, free, and fatherly God, for science has convinced me that such a being cannot possibly exist"; another: "I must necessarily believe in a personal God, for science has, in speculative dogmatics, irrefutably proved that God is personal"—then both make themselves guilty of one and the same misapprehension of subjectivity's share in the demonstration.

No personally coherent view of life is possible without faith, no essential faith is

possible without decisive self-determination, no decisive self-determination is possible without a choice, no choice is possible without a self-consciously choosing subjectivity responsible for its choice. Could such a preponderance of subjectivity in the religious be supposed to stand in conflict with science and sound reason?

Science can do no more than lay before consciousness the possibilities between which a choice must be made, and illuminate the real grounds; but transform the grounds into motives, determine the specific weight of the motives, and exempt subjectivity from the responsibility of the choice, it cannot. It might well seem as though the responsible subjectivity now became at once so independent and self-willed that it could prefer a view of life as mythically fantastic as it liked, without owing either science or reason any account for it. This is indeed also the case with such individualities as do not see what science actually is, and in whom reason is still a minor child; but it by no means holds of those who have made a deeper insight into the essence of science. Even when, from inner personal need, they choose to believe in the revealed religion and preserve the inherited reverence for the Church and its institutions, they must constantly render account to science, in that they render account to themselves; in no case may man arbitrarily extinguish the light of reason, but reason's pure light burns clearest in science.

It then becomes a life-task *to unite religious faith with scientific consciousness.* How is this possible? The positive content that is appropriated in faith cannot, as Littré assumes, be fetched from science; and yet the scientific consciousness must, so far as it is able, take part in subjecting this content to a critical examination. We meet here, on the highest stage of the spiritual life, again the double-sided functions. The purifying criticism is at once a faith-criticism and a science-criticism. The faith-criticism separates out all that does not originally concern the essence of faith; the whole apparatus of tradition in outward historical form it regards as a clothing, a husk, in which the holy content is preserved. It by no means wishes to disparage the clothing or break apart the husk; but it will nevertheless appropriate only what the believing subjectivity, from inner experience, needs as an indispensable condition for the development of its freedom-life. How the science-criticism is present everywhere can be known from the apprehension and evaluation of what is handed down. We can

illuminate the reciprocal action under the standpoint of the two categories: possibility and probability.

The improbable must be believed, but the impossible cannot be believed—that is a fundamental principle for all revelation-faith. The revelation-faith presupposes the miracle's possibility, science stands firm on the miracle's improbability; but Faith and Knowledge agree in distinguishing between possibility and actuality. The miracle's possibility points toward what we must call the perennial wonder, that is, toward the general presupposition that the eternal self-power continuously stands in a freedom-relation, an actual will-relation, to the natural order of things, in which everything takes place according to laws. That rational knowledge can raise no warranted objection against this has been shown in the foregoing.

It would look more precarious if the believing subjectivity, in enthusiastic rashness, set about reasoning thus: "If the spirit is almighty and free, then the absolutely free self-power must, after all, be able to change nature's course at pleasure; the real miracles then stand as testimonies of an unsearchable almighty-will; one must either accept them or reject them unconditionally; here there can be no question of criticism, here only faith or unbelief holds." But the reasoning that thus annihilates all criticism is itself uncritical and false. In an abstract outward, objective sense it is quite true that real miracles withdraw themselves from all criticism; but in such an outward, blind facticity the real miracles have no significance either, neither for Faith nor for Knowledge: they stand as phenomenal monstrosities, absolutely incomprehensible *τέρατα*. In the moment that a comprehensible meaning, a religious significance, is ascribed to them, the subjective comes into movement, and the finite relation between subjectivity and the objective actuality entitles us to a historical use of the measure of probability.

No real miracle has ever been demonstrated by compelling historical testimonies. The miracle is an outward sign of an essential inward, of freedom's power over necessity, of life's victory over death; the miracle is sign and symbol, and becomes no more, even if its actuality were confirmed by ten thousand sworn eyewitnesses. The given sign is at once an inner and an outer fact; the inner is the ideal in the actuality, the essential faith-content, the outer is the wonderful phenomenon that

makes visible the presence of the inner. The inner, the essential, is the extraordinary of freedom and love, that which is improbable for the finite understanding, which can be appropriated subjectively, tested subjectively, and be present to consciousness at all times; the outward, the phenomenal, is the past, it belongs to a definite time, and the age's more or less adequate apprehension of it is to be determined by approximation according to probability. The faith-criticism can then appropriate the improbable but yet possible, and the science-criticism, as regards this possible's outer appearance, hold to the probable, and both agree that the miraculous in the sign is *spirit-reality, reality for the spirit*. Spirit-reality means that here there really is a faith-content, an unambiguous revelation of the divine will; reality for the spirit means that the outer may not be held fast in so sensibly immediate an outwardness that there can be talk of a breach of nature's laws.

That one, from an exclusively objective, scientific standpoint, must regard such an interpretation of the revelation-phenomena, indeed of the essence of revelation, as veiled and ambiguous, is quite in order²⁰. Since here it is a question of science-criticism,

²⁰Knowledge's fundamental principle is that nothing may be assumed to be real which demonstrably conflicts with the law of reality. Faith's fundamental principle is that a real sign of the saving omnipotence may not be declared impossible because it makes an exception to the laws known to us. Christ's resurrection is an eloquent example. Without science-criticism the believer will, in all credulity, take the outward in the event for something so real that the continuity of law is broken, and that so conspicuously that the one miracle comes to contain at least six miracles. Without faith-criticism the knower will unconditionally reject an actuality that six times contradicts itself, and assign it a place in the world of imaginings. If an honest reconciliation between Faith and Knowledge is to be possible, then it must be seen that here there is right and wrong on both sides. The believer is right insofar as he holds fast the fact as a real sign of omnipotence; but when he then, relying on mutually discordant accounts, apprehends the real in such a way that it becomes a sign of the unbounded arbitrariness with which the almighty freedom can turn all the laws of nature and spirit upside down, and makes such a sign of arbitrariness into a sign of salvation, then he is grossly wrong. The knower is right in that he asks, for all actuality, about laws of actuality, and guards himself against assuming anything whatever for a real fact when the laws contradict one another; but when he then swears by a natural-necessity whose conditions experience has secured for him only by empirical induction, to such a degree that he *a priori* denies freedom's possibilities, then he is wrong, even in science. And what then becomes the result? That there can be facts of so peculiar a nature that the kernel, the essential content, may not be denied, and moreover of so extraordinary an appearance that the outer form of the actuality cannot possibly be definitively determined. If now such a fact stands in a contingent relation to the religious faith, then it can find its place among myths and legends; if, on the other hand, it contains a truth decisive for the faith-life, then the sensible outer must be apprehended as a phenomenon making visible, a sign and symbol of the real inner; in other words: the fact must be determined as *spirit-reality, reality for the spirit*. The question of spirit-reality is, as one will see from this, not a personal faith-question, but an objective knowledge-question. How the believer comes to terms with himself about the fact's

one forgets every moment where we are, and demands the impossible—demands that the fact itself shall be scientifically proved. That is a thoughtlessness. The science-criticism is, so to speak, only present in the probate court in order to secure the apprehension against warranted objection, while the faith-criticism asserts its own peculiar principle, absolutely heterogeneous with the objectivity of knowledge, and faith appropriates the inheritance.

Religious faith is, in its first immediacy, a faith in something historical, an authority-faith that stands firm on a holy, infallible tradition; the naive faith will hear nothing either of probable and improbable or of the difference between outer and inner, it demands certainty, historical certainty. Since now one or another outward authority goes surety for the historical certainty without entering upon critical investigations, it happens that faith from the beginning gets an admixture of superstition, an admixture that is extremely difficult to separate out when the faith-truth itself is to be preserved. If an outward authority is to vouch for the truth, then the criterion of truth is lost; for the authority acts not convincingly, but imposingly. Every faith-community will then come forward with its myths and its miracles and set about impressing the unstable soul; here there is then no question of which of the many religions has the deepest content of truth, but of which of them, by its signs and symbols, has the best hold for impressing. It is a distinguishing mark of the revealed—i.e. the *subjectively spirit-clear*—religion, that it, through the outward authority, everywhere in the name of truth points toward the inward, toward the spirit's authority, the spirit's testimony.

Thus, then, the doctrine of two absolutely heterogeneous principles is by no means any directive to tear religion loose from science, or faith from reason; the dualistic separation is precisely the condition for attaining a reconciling unity: of Faith and Knowledge too it holds that opposite poles attract one another.

outer historical actuality must be his own affair; only this stands fast: he cannot possibly have the science-criticism with him without recognizing law-determined boundaries, boundaries that cannot be overstepped without *self-contradiction* setting in.
